

Novel Hybrid Genetic Arithmetic Optimization for Feature Selection and Classification of Pulmonary Disease Images

Nivetha S., Department of Computer Science, Periyar University, Salem, India*

Hannah Inbarani H., Department of Computer Science, Periyar University, Salem, India

ABSTRACT

The difficulty in predicting early cancer is due to the lack of early illness indicators. Metaheuristic approaches are a family of algorithms that seek to find the optimal values for uncertain problems with several implications in optimization and classification problems. An automated system for recognizing illnesses can respond with accuracy, efficiency, and speed, helping medical professionals spot abnormalities and lowering death rates. This study proposes the Novel Hybrid GAO (Genetic Arithmetic Optimization algorithm based Feature Selection) (Genetic Arithmetic Optimization Algorithm-based feature selection) method as a way to choose the features for several machine learning algorithms to classify readily available data on COVID-19 and lung cancer. By choosing just important features, feature selection approaches might improve performance. The proposed approach employs a Genetic and Arithmetic Optimization to enhance the outcomes in an optimization approach.

KEYWORDS

Arithmetic Optimization, CNN Features, Computed Tomography, Genetic Algorithm, Metaheuristic Approaches, Novel Hybrid GAO

1. INTRODUCTION

The most common cancer that claims lives in both men and women is lung cancer. According to American Cancer Society statistics, there are 220,000 new cases each year, 160,000 people die from the disease, and 15% of people with all stages of the disease survive for 5 years. However, the localized stage has a 5-year longevity rate of roughly 50%. In the localized stage, cancer does not spread outside the body, such as to lymph nodes (Aboamer et al., 2019; Ajeil et al., 2020a; Habibifar et al., 2019) The specific kind of tumors as well as additional factors like prognostics general health, etc., all have an impact on the 5-year survival rate. The main determinant of lung cancer survival rate is early recognition. Before lung cancer spreads to other parts of the body, symptoms do not manifest in the lung. Lung cancer is detected using various techniques, including microarray data analysis, sputum analysis, Computed Tomography (CT) scans, and chest radiography. Lung cancer identification with widespread chest CT screening is a promising technique.

A recent infectious disease called COVID-19 has been circulating all over the world (Azar & Hassani, 2022; Abbas et al., 2022; Abdelmalek et al., 2018). The pandemic has had several health impacts, including economic loss, disruption of communication and information systems, social distancing, and quarantine procedures. Quarantine is an example of a confinement policy used to maintain a safe distance between people. The isolation step involves the treatment of people with suspected symptoms so that they can return to normal conditions; governments maintain medical facilities during this phase.

Along with the extensive usage of Machine Learning and Deep Learning approaches, the various feature selection methods have been utilized in statistics and pattern recognition for several years. (Waleed et al., 2022; Wen et al., 2022; Aboamer et al., 2014b; Acharyulu et al., 2021; Ahmadian et al., 2021; Ajeil et al., 2020b; Hamida et al., 2022a; Azar, 2020a,b). When there was an excessive amount of data that needed to be processed quickly, feature selection techniques were necessary (Azar et al., 2023d). These feature selection techniques were utilized to achieve the objectives of increasing classifier accuracy, decreasing dimensionality, removing superfluous and unrelated data, and more. It also aided in enhancing data comprehension and reducing the time required to run learning algorithms.

Deep learning techniques make very small elements in images visible that would not otherwise exist. “Convolutional Neural Networks (CNNs)” are the top excellent among academics for classification-related tasks in medical imaging issues because of their prowess in deep feature extraction and learning. CNNs are useful for detecting the features that discriminate different objects from each other. (Aboamer et al., 2014a; Ali et al., 2022b). However, CNNs are not suitable for applications with high learning capacity and large amounts of data as they are very sensitive to hyperparameters. Moreover, it is needed to consider the amount of data, since neural networks have a large complexity and require much time to process a dataset. These factors can make it challenging for practitioners to manually adjust these hyper-parameters so that they can be optimized effectively.

A heuristic is a method designed to solve a problem more quickly when more conventional methods are inefficient. (Ajeil, et al., 2020a; Al-Qassar et al., 2021a; Amara et al., 2019; Elkholy et al., 2020a; Azar & Banu, 2022). A black-box optimizer known as a meta-heuristic algorithm is given a collection of issue variables, including some restrictions in the form of limitations. The optimizer changes these variables by performing an updating procedure up until it finds an objective function’s optimal value. The result is a close-to-optimal solution that has the objective function’s maximum and minimum values. The objective is to find the best answers in a fair amount of time with the least amount of computational complexity.

Combinations of Genetic Algorithms and Arithmetic Optimisation Algorithms-based feature selection approaches are used in this work to increase the efficiency of machine learning algorithms for lung cancer and COVID classification. Genetic Algorithm (GA) and Arithmetic Optimisation Algorithm (AOA) are two methods that can be used in combination to solve optimization problems. AOA focuses on performing mathematical operations to optimize each solution, whereas GA uses population-based search and genetic operators like mutation and crossover. In this hybrid approach, a population of individuals representing potential solutions is formed using a genetic algorithm as the fundamental framework. The hybrid GA with the AOA technique can be a potent method for resolving challenging optimization issues, using the advantages of both methods to produce superior results.

1.1 Background Study for Metaheuristic Algorithm

Metaheuristics are a class of optimization techniques that provide versatile and efficient solutions to complex problems across various domains (Hussien et al., 2023; Ganguly et al., 2023; Hussain et al., 2023; Ali et al., 2022a; Abdul-Kareem et al., 2022; Sekhar et al., 2022; El Kafazi et al., 2021; Azar and Serrano, 2019, 2020d; Elkholy et al., 2020b; Mohamed et al., 2020a; Ben Smida et al., 2018; Akyol & Alatas, 2017). By drawing inspiration from natural processes, such as evolution, swarm behavior, and annealing, metaheuristics navigate solution spaces to discover high-quality solutions that traditional methods might struggle to find. These algorithms, which include genetic algorithms,

particle swarm optimization, simulated annealing, and ant colony optimization, offer a balance between exploration and exploitation, enabling them to tackle optimization challenges with irregular, nonlinear, or multi-modal landscapes. While not guaranteed to find the global optimum, metaheuristics excel in finding satisfactory solutions within reasonable timeframes, making them invaluable tools for solving real-world problems in engineering, logistics, finance, and beyond. They can be broadly alienated into deuce classes: neighborhood-based algorithms and population-based algorithms.

Neighborhood-Based Algorithms are metaheuristics exploration and change solutions in the immediate locality of the present solution to iteratively probe the exploration space. Population-based algorithms are metaheuristic algorithm as it is more commonly known, provides a universal optimization basis that is easily adaptable to a variety of optimization problems by discovering and manipulating the search space through the use of operators and carrying out operations, such as parameter tuning and modification. A few of these sources of inspiration are “Swarm-Inspired,” “Chemistry-Inspired”, “Human-Inspired”, “Plant-Inspired”, “Maths-Inspired” and “Physics-Inspired”.

The first class of population-based natural metaheuristics is called swarm-inspired metaheuristics. Swarms imitate a variety of societal animal behaviors, such as the foraging behavior of ants, the flocking behavior of birds, the schooling behavior of fish, the moulting behavior of bacteria, and the herding behavior of animals, among many others. Some of the swarm-inspired algorithms are given below, “Ant Colony Optimisation” (Dorigo et al., 1999; Asad et al., 2013a,b, 2014a,b; Dey et al., 2015; Moftah et al., 2014), “Cuckoo Search” (Yang & Deb, 2010), “Artificial Bee Colony” (Karaboga, 2010), “Particle Swarm” (Kennedy & Eberhart, 1995), “Firefly” (Yang & He, 2013), Krill Herd (Wang et al., 2014), Bat (Yang & Gandomi, 2012), Manta Ray Foraging Optimisation (Zhao et al., 2020), Moth-Flame Optimisation (Mirjalili, 2015), Dragonfly (Mirjalili, 2016a), Marine Predators (Faramarzi et al., 2020a), Grey Wolf Optimisation (Emary et al., 2015), (Nivetha et al., 2021a) and Whale Optimisation (Mirjalili & Lewis, 2016) are a few examples of optimization algorithms.

The second class of “population-based” nature-inspired metaheuristics, called Chemistry-Inspired metaheuristics, draws its primary source of inspiration from the nature of chemical processes to solve contemporary challenges. This area includes techniques like “Chemical Reaction Optimisation” (Lam et al., 2012), “Henry Gas Solubility Optimisation” (Hashim et al., 2019), and “Artificial Chemical Reaction Optimisation” (Alatas, 2011).

A third kind of “population-based”, naturally inspired metaheuristics called “human-inspired” models human dominance, IQ, and behavior. The algorithms “Imperialist Competitive Algorithm” (Atashpaz- Gargari et al., 2007), “Human Mental Search” (Azar et al., 2020b; Mousavirad et al., 2017), “Search and Rescue Optimisation” (Shabani et al., 2020), “Election Algorithm” (Emami & Derakhshan, 2015), “Gaining Sharing Knowledge-Based Algorithm” (Mohamed et al., 2020b), “Forensic-Based Investigation Optimisation” (Shaheen et al., 2020), “Brain Storm Optimisation” (Shi, 2011), “Teaching Learning-Based Optimisation” (Rao et al., 2011), “Class Topper Optimisation” (Das et al., 2018), and “Football Game Algorithm” (Fadakar & Ebrahimi, 2016), and “Life Choice-Based Optimisation” (Khatri et al., 2020), “Coronavirus Herd Immunity Optimization” (Al-Betar et al., 2021) and “Battle Royale Optimization” (Rahkar, 2021).

Plant-Inspired “population-based” nature-inspired metaheuristics, the fifth class of metaheuristics, fundamentally mimic the intelligent behavior exhibited by plants. These are only a few of the well-known plant-based algorithms: “Plant Growth Optimisation” (Cai et al., 2008), “Plant Photosynthetic Algorithm” (Murase et al., 2000), “Plant Propagation Algorithm” (Salhi & Fraga, 2011), “Artificial Plant Optimization Algorithm” (Cui et al., 2013), “Paddy Field Algorithm” (Kong et al., 2012), “Fertile Field Algorithm” (Mohammadi et al., 2020), “Flower Pollination Algorithm” (Yang et al., 2013), “Path Planning Inspired by Plant Growth” (Zhou et al., 2017), “Invasive Weed Optimisation” (Karimkashi & Kishk, 2010), “Rooted Tree Optimisation” (Labbi et al., 2016), “Sapling Growing up Algorithm” (Karci et al., 2007), and “Root Growth Algorithm” (Zhang et al., 2014) are some examples of algorithms.

The sixth category of population-based, nature-inspired meta-heuristic optimization is the Math-Inspired category, which essentially tends to replicate the approach of numerical techniques, mathematical programming, and its emphasis on resolving a range of constraints and optimization issues in the actual world. The “Hyper-Spherical Search Algorithm” (Karami et al., 2014; Azar et al., 2020o), “Radial Movement Optimisation” (Rahmani & Yusof, 2014), “Stochastic Fractal Search” (Salimi, 2015), “Golden Ratio Optimisation Method” (Nematollahi et al., 2020), “Sine Cosine Algorithm” (Mirjalili, 2016b) and “Arithmetic Optimisation Algorithm” (Abualigah et al., 2021; Azar et al., 2020f,g) are a few well-known algorithms that draw inspiration from mathematics.

Physics-Inspired meta-heuristic optimization is the final class of “Population-based Nature-Inspired meta-heuristic optimization”. Physics-Inspired in which the main source of inspiration is the physical processes, which are further formulated into solutions to resolve the problems. A few popular physics-inspired algorithms are “Equilibrium Optimizer” (Faramarzi et al., 2020b), “Multi-Verse Optimization” (Mirjalili et al., 2016; Azar and Kamal, 2021a,b,c; Azar et al., 2021), “Bang-Big Big-Crunch Algorithm” (Erol et al., 2006), “Magnetic Charged System Search” (Zhao et al., 2019), “Central Force Optimization” (Formato, 2007), “Thermal Exchange Optimization” (Kaveh & Dadras, 2017), “Ray Optimization” (Kaveh & Khayatazad, 2012), “Gravitational Search Algorithm” (Rashedi et al., 2009), “Artificial Physicomimetics Optimization” (Xie et al., 2010), “Optics Inspired Optimisation” (Kashan, 2015), “Electromagnetic Field Optimization” (Abedinpourshotorban et al., 2016), “Gravitational Local Search Optimization” (Rashedi et al., 2018) and “Electromagnetism-like Algorithm” (Birbil et al., 2003; Azar et al., 2023a).

1.2 Problem Formulation and Motivation

Image processing approaches that include Deep Learning aid in the detection of cancer utilizing image processing technologies (Azar et al., 2018b; 2020; Chowdhuri et al., 2014a; Inbarani et al., 2015a; Hassanien & Azar, 2015; Mjahed et al., 2020; Kumar et al., 2018). The optimization of complicated, high-dimensional problems is the issue that the hybrid technique combining Genetic Algorithm (GA) and Arithmetic Optimisation Algorithm (AOA) seeks to address. Finding the ideal set of characteristics or variables to maximize or minimize a specific objective function is a common task in these issues. However, it might be difficult to effectively examine the enormous search field for these issues.

1. **Accuracy and diagnosis errors in medical applications:** Lower accuracy, increase Classification accuracy, and lower diagnostic errors.
2. **Avoiding local minima and overfitting:** In integrated optimization designs, avoid overfitting, get to the optimum local optima without becoming stuck, and strike a balance between exploitation and exploration.
3. **Optimise parameters:** To obtain global optimality and steer clear of suboptimal solutions when solving optimization problems.
4. **Scalability for complex issues:** To efficiently address high-dimensional and large-scale problems, develop scalable optimization strategies.
5. **Time complexity and convergence speed:** Improve convergence speed while keeping the quality of the solutions.

1.3 Motivation

1. **Develop a hybrid framework:** Propose a hybrid framework that combines Genetic Algorithm (GA) and Arithmetic Optimization Algorithm (AOA) to enhance optimization performance.
2. **Feature selection:** Incorporate an approach for choosing the finest subclass of features, leveraging metaheuristic approaches to efficiently handle the NP-hard task of feature selection.
3. **Enhance performance:** Improve solution quality, accelerate convergence, and enable effective exploration of the solution space through the integration of GA and AOA.

4. **Complexity handling:** Address the complexity of feature selection by utilizing metaheuristic approaches that efficiently navigate high-dimensional feature spaces.
5. **Evaluation and comparison:** Evaluate and compare the proposed hybrid framework with existing optimization methods using metrics such as solution quality, convergence speed, and computational efficiency.
6. **Practical applications:** Explore practical applications in domains such as medical diagnosis, data mining, or engineering design to reveal the efficiency and pertinence of the hybrid framework.

This study will offer a hybrid framework that combines two optimization strategies GA and AOA. A method for choosing the optimum subset of characteristics is essential to progress the recital of the framework. It is advised to employ metaheuristic methods to choose the superlative subset of features because feature selection is an NP-hard problem.

1.4 Research Contribution

The Novel Hybrid GA-AOA algorithm is used in this study to identify and categorize lung cancer in COVID images. This technique increases the effectiveness of AOA. To solve the feature selection problem, the research paper suggests a hybrid technique that combines the GA and AOA algorithms. By integrating the exploration capabilities of GA with the fine-tuning abilities of AOA, the algorithm aims to enhance exploitation and improve efficiency. The method uses a customized location update formula that alternates between GA and AOA at random to create an equilibrium between exploration and exploitation. This enables comprehensive exploration of the solution space while leveraging the promising solutions discovered.

Through iterative iterations, the algorithm refines the feature selection process by combining GA and AOA. It explores various feature subsets and optimizes their selection based on the fitness function. This iterative approach enables the identification of the most relevant and discriminative features for effective classification. The methodology involves generating an initial population using GA and then iteratively applying AOA and GA to enhance the population's fitness. The fitness function, evaluated using a classifier like Random Forest, assesses the accuracy of the selected features. The algorithm replaces inferior individuals in the population with offspring generated through crossover and mutation operations. The research study validates the efficiency of the Novel Hybrid GAO method through comparative evaluations with other feature selection techniques. This demonstrates the algorithm's prowess in navigating the problem space, achieving high-quality feature subsets, and striking a steadiness between exploration and exploitation.

1. **Novel Hybrid GAO Framework:** The research proposes a hybrid algorithm that combines “Genetic Algorithm (GA)” and “Arithmetic Optimization Algorithm (AOA)” to improve the optimization progression.
2. **Feature Subset Selection:** The algorithm incorporates feature subset selection to identify the most relevant features for improving solution quality.
3. **Enhanced Solution Quality:** The hybrid approach enhances the solution quality by leveraging the fine-tuning capabilities of AOA and the exploration capabilities of GA.
4. **Avoiding Local Optima:** The hybrid algorithm overcomes the issue of getting trapped in local optima by combining GA and AOA, allowing for the exploration of global solutions.
5. **Improved Convergence Speed:** The hybrid algorithm achieves faster convergence by leveraging AOA's convergence properties and GA's population-based search.
6. **On the COVID dataset and the lung cancer dataset:** The proposed technique yields the best results.

To provide a clear grasp of the existing methodology's examine in Section 2. Section 3 explains Our suggested technique and provides details on its conceptual foundation and layout. The full

explanation of Feature Extraction Using CNN is provided in Section 4 followed by explanation of essential methods and important components of our proposed approach. The subtleties of hyperparameter tweaking are explained in Section 5, offering light on the process of fine-tuning that improves the performance of proposed model. In Section 6, highlights the useful implications of our proposed research, describing the experimental results and outcomes of applying our recommended methodology. Summarization of the proposed research work and conclusion is presented in Section 7.

2. RELATED WORK

Artificial Intelligence (AI) stands as the overarching field that encompasses computational intelligence, metaheuristic algorithms, control and robotics, forming a dynamic and interconnected landscape of technological advancement (Ahmed et al., 2023a,b,c, 2022a,b; Sayed et al., 2023; Sergiyenko et al., 2023; Vaidyanathan et al., 2023, 2019, 2018a,b, 2017a,b, 2015; Kengne et al., 2023a,b; Azar et al., 2023b,d, 2022a,b, 2020a,i,j,k; Hashim et al., 2023; Hameed et al., 2023; Fekik et al., 2023a,b,c, 2022a,b,c, 2021a,b,c,d,e; Zhang et al., 2023; Wang et al., 2023; Dendani et al., 2023; Bousbaine et al., 2023; Hasan et al., 2023; Hamida et al., 2023, 2022b; Naoui et al., 2023). Artificial intelligence (AI) is rapidly transforming the field of robotics, enabling robots to perform more complex tasks and operate in more challenging environments. AI techniques such as machine learning, computer vision, and natural language processing are being used to develop robots that can learn, adapt, and make decisions on their own. This is making robots more versatile and reliable, and opening up new possibilities for their use in a wide range of applications, such as manufacturing, healthcare, and customer service.

For example, AI-powered robots are being used in factories to automate tasks such as welding, assembly, and painting. These robots can learn to perform these tasks more efficiently than human workers, and they can operate 24/7 without getting tired. AI-powered robots are also being used in healthcare to perform tasks such as surgery and rehabilitation. These robots can be more precise and gentler than human surgeons, and they can provide personalized care to patients. AI is also playing a major role in the development of new control systems for robots. Traditional control systems are based on pre-programmed instructions, which can be limiting in complex and dynamic environments (Vaidyanathan et al., 2021a,b,c,d,e,f; Sambas et al., 2021a,b,c; Drhorhi et al., 2021; Alimi et al., 2021; Kumar et al., 2021; Bansal et al., 2021; Singh et al., 2021a, 2018, 2017; Gorripotu et al., 2021; Ouannas et al., 2021, 2020a,b,c, 2019, 2017a,b,c,d; Khennaoui et al., 2020). AI-based control systems can learn and adapt to changes in the environment, making them more robust and reliable (Pham et al., 2018; Shukla et al., 2018; Vaidyanathan & Azar, 2016a,b,c,d,e,f,g, 2015a,b,c; Azar & Serrano, 2015). This is making it possible to develop robots that can operate in more challenging environments, such as those that are hazardous or unpredictable.

For example, AI-based control systems are being used to develop robots that can navigate through cluttered or unstructured environments (Najm et al., 2021a,b). These robots can learn to avoid obstacles and plan their own paths, making them ideal for applications such as search and rescue. AI-based control systems are also being used to develop robots that can interact with humans in a safe and effective way. These robots can learn to recognize human gestures and respond appropriately, making them suitable for applications such as customer service and education.

Computational intelligence techniques, including neural networks, fuzzy logic, and genetic algorithms, contribute to the development of AI by enabling machines to learn from data and make informed decisions (Djeddi et al., 2019; Abdelmalek et al., 2021; Meghni et al., 2017a, 2018). In tandem, metaheuristic algorithms, such as genetic programming and particle swarm optimization, empower AI systems to solve complex problems by mimicking natural processes of optimization and exploration. Robotics, on the other hand, serves as the embodiment of AI in the physical world, leveraging computational intelligence and metaheuristics to create intelligent machines capable of autonomous action and interaction with their environment (Al Mhdawi et al., 2022; Toumi et al., 2022;

Abed et al., 2022; Daraz et al., 2022, 2021; Mahdi et al., 2022; Najm et al., 2022; Abdul-Adheem et al., 2022, 2021, 2020a,b; Humaidi et al., 2023, 2022; Saidi et al., 2022; Ghoudelbourg et al., 2022, 2021, 2020, 2016; Ajel et al., 2021; Bouchemha et al., 2021; Rana et al., 2021; Lajouad et al., 2021; Al-Qassar et al., 2021b; Hamiche et al., 2021; Ibraheem et al., 2020a; Kammogne et al., 2020; Alain et al., 2020; Ghazizadeh et al., 2018). Together, these components epitomize the multifaceted nature of AI, driving innovation and reshaping the boundaries of technological possibility.

In recent years, computer vision research has grown to be a significant area of study in the biomedical field (Anter et al., 2020; Azar et al., 2019b; Chowdhuri et al., 2014b; Inbarani et al., 2014a; Kumar et al., 2014a). X-ray images and Computed Tomography (CT) scan images are both kinds of images employed in COVID-19 detection studies. X-ray images and Computed Tomography (CT) scan images are used for different purposes. X-ray images capture dense tissues in addition to soft tissue and bones, while CT scans capture many details of the body in one image. In addition to these two types of images, some studies use only one type or the other, while others use both.

A dataset's behavior is determined by its collection of characteristics, and in the case of image datasets, some features are very important. (Ananth et al., 2021; Anter et al., 2013; Azar et al., 2018a; Hassanien et al., 2015). To correctly classify an image, it is essential to consider its size, color values, intensity, and presence of distinct shapes. Images have thousands of features because of the enormous number of pixels they contain, which increases computing complexity. It is therefore crucial to reduce the number of features in image data before submitting it to a classification system. The core traits must be kept; hence it is equally crucial to protect the fundamental patterns of each class throughout this feature reduction procedure. Additionally, the quantity of pixels in an image directly correlates with its quality.

Algorithms are essential in the fields of machine learning and deep learning for locating specific patterns or recurring structures within data points, particularly in image datasets (El-Shorbagy et al., 2023; Anter et al., 2014, 2015; Ashfaq et al., 2022a; Aslam et al., 2021; Azar et al., 2019c; Boulmaiz et al., 2022; Cheema et al., 2020). However, the raw data needs to be thoroughly cleaned to remove any extraneous information before beginning the discovery process. Here, the feature extraction stage comes in handy since it draws out key details from the data, including edges, corners, or distinct visual areas. This stage is constantly emphasized in the literature as coming first after preprocessing. The Convolutional Neural Network (CNN) stands out as the most extensively used approach among the numerous feature extraction techniques because it effectively extracts useful characteristics from images. Using CNN, the algorithm can quickly recognize important patterns and information necessary for accurate classification tasks (Ashfaq et al., 2022b; Azar et al., 2019a; Inbarani et al., 2014c ; Soliman et al., 2020).

Chen and Chiang (2023) proposed a method for optimizing the hyperparameters of a CNN model for COVID-19 diagnosis. The method uses a genetic algorithm to search for the best combination of hyperparameters. The model was trained on a dataset of 5,000 CXR images, and it achieved an accuracy of 97.56% in classifying COVID-19, normal, and pneumonia patients.

In Nitha et al. (2023), Transfer learning is used to create the ExtRanFS framework for automated lung cancer malignancy diagnosis. The dataset's CT images have a slice thickness of 1mm and are made up of 80 to 200 slices that were collected from various perspectives and sides. The “DICOM” format is used to store all images. The suggested solution used a pre-trained “VGG16” model based on convolution as the feature extractor and an “Extremely Randomised Tree Classifier” as the feature selector. The “Multi-Layer Perceptron (MLP)” Classifier uses the chosen features to determine if lung cancer is “benign, malignant, or normal”. The proposed framework has an “accuracy, sensitivity, and F1-Score of 99.09%, 98.33%, and 98.33%”, respectively.

In Prasad et al. (2023) the study's solution to feature selection issues used the Hybrid Spotted Hyena Optimisation with the Seagull Algorithm, which successfully produced the ideal subset with the greatest number of pertinent features. To do data augmentation, we used DCGAN, a generative modeling technique. Utilizing a “hybrid CNN-LSTM” that discovered both standard and aberrant

structures in biological lung data, the selected lung characteristics are assessed. The structure's effectiveness is evaluated by looking at its "accuracy, precision, recall, specificity, and sensitivity". The suggested classifier achieved 99.8% sensitivity, 99.3% specificity, 99.14% precision, and 99.6% accuracy in the "LIDC/IDRI" database. The classifier attained a "sensitivity" of 99.62%, "specificity" of 97.8%, "precision" of 97.5%, and "accuracy" of 99.7% in the chest X-ray dataset.

Deepa and Shakila (2022) proposed a CNN-based model for classifying COVID-19 X-ray images. The model is optimized using a hybrid optimization algorithm that combines the Firefly Algorithm and Particle Swarm Optimization. The model achieves an accuracy of 93.33% on a test dataset of 100 images.

Canayaz (2021) used images from three kinds of patients: pneumonia patients, COVID patients, and normal patients. Deep learning models like "AlexNet", "VGG19", "GoogleNet", and "ResNet" were used to complete the feature extraction process from this data set. Two metaheuristic algorithms "Binary Particle Swarm Optimization" and "Binary Grey Wolf Optimization" were applied to choose the best possible features in the classification pipeline. Using SVM, these chosen features were categorized. It was successful in achieving 99.38% accuracy.

Goel et al. (2021) proposed a CNN model that is optimized using Grey Wolf Optimization (GWO). The model was trained on a dataset of 3,000 CXR images, and it achieved an accuracy of 97.78% in classifying COVID-19, normal, and pneumonia patients.

In Singh et al., (2021b) "binary class classifier", feature selection was carried out using "HSGO (Hybrid Social Group Optimisation)", and the classifier was trained on "chest X-rays". SVM (Support Vector Machine) surpassed all other classifiers in tests using these chosen features, obtaining a remarkable accuracy of 99.65%. Multiple classifiers used the relevant features that were found through feature extraction from "CXR images" to help them classify the images. Surprisingly, this proposed pipeline outperformed other cutting-edge deep learning methods for both "binary and multi-class classification", obtaining a remarkable "Support Vector Classifier" classification accuracy of 99.65%.

ResNet18 (CNN) remained by Chattopadhyay et al. (2021) to feature extraction, and the most pertinent characteristics were then chosen from the extracted features using the CGRO. A subset of the crucial features was chosen, and SVM was then applied to carry out the classification. On both CT and X-ray pictures, this model was put to the test. The studies used the "SARS-COV-2 dataset", "the Chest X-Ray dataset", and the "CT dataset" to produce outcomes with accuracy levels of 98.65%, 99.44%, and 99.31%, respectively.

A "Convolutional Neural Networks (CNN)" approach for identifying COVID-19 patients based on chest X-ray images was introduced by Shukla et al. (2021) in their work. They used "GoogLeNet", a pre-trained model with part of its final CNN layers altered, to implement transfer learning. A method called 20-fold cross-validation was proposed to solve overfitting issues. The suggested COVID-19 detection model for chest X-ray pictures hyperparameters was also fine-tuned using a "multi-objective genetic algorithm". This model's testing and training accuracy reached astounding results, coming in at 98.3827% and 94.9383%, respectively.

Yousri et al. (2021) used "discrete and Gabor wave transformations" which resulted in the computation of the "Grey Level Co-occurrence Matrix (GLCM)". An enhanced "Cuckoo Search optimization method (CS)" replaces the "Levy flight with four separate heavy-tailed distributions" to enhance the performance of the system when handling the COVID-19 multiclass classification optimization job. "18 UCI data sets" were used as the initial series of tests to validate the suggested FO-CS variants. Two data sets, COVID-19 for X-ray pictures are taken into consideration for the second series of tests. The findings of the suggested approach have been contrasted with those of reputable optimization algorithms. On dataset 1 they were able to reach 84.67%, and on dataset 2 98.95%.

In Iraji et al. (2021) study, a hybrid method grounded on "Deep Convolutional Neural Networks" powerful tools for picture classifying is presented. "Deep Convolutional Neural Networks" were utilized to excerpt feature vectors from the images, and the "binary differential metaheuristic algorithm" was then applied to choose the utmost advantageous features. These improved characteristics were then

applied to the SVM classifier. A repository of 1092 X-ray samples from three categories- “COVID-19”, “pneumonia”, and a “healthy category” was used in the investigation. With “accuracy, sensitivity, and specificity” reaching 99.43%, 99.16%, and 99.57%, respectively, the suggested technique performed quite well. Interestingly, Our results showed that the suggested strategy outperformed current studies on “COVID-19 recognition using X-ray imaging”.

Lakshmanaprabu et al. (2019) proposed “Linear Discriminate Analysis (LDA)” and “Optimal Deep Neural Network (ODNN)” to analyze the CT scan lung pictures. LDR is used to lower the dimensionality of the deep features retrieved from “CT lung images” before classifying lung nodules as either benign or malignant. To classify lung cancer, the ODNN is applied to CT images and then optimized using the “Modified Gravitational Search Algorithm (MGSA)”. According to comparison data, the proposed classification has a “sensitivity of 96.2%”, “a specificity of 94.2%”, and an “accuracy of 94.56%”.

Pradhan et al. (2023) proposed a Convolution Neural Network (CNN) to determine if a chest X-ray (CXR) image exhibits pneumonia (Normal) or COVID-19 disease. Furthermore, in order to improve the CNN classifier’s performance, a nature-inspired optimisation approach known as the Hill-Climbing Algorithm based CNN (CNN-HCA) model has been presented to improve the CNN model’s parameters.

Shan & Rezaei (2021) proposed Lung cancer automatic and optimized computer-aided detection. The preprocessing step of the procedure involves normalizing and denoising the input images. After that, lung region segmentation is carried out using mathematical morphology and Kapur entropy maximization. The segmented pictures are then used to obtain 19 GLCM features for the final analyses. To reduce system complexity, higher-priority images are then chosen. This feature selection is centered on a novel optimization method called “Improved Thermal Exchange Optimisation (ITEO)” and aims to increase exactness and convergence. The imageries are then categorized into cancerous or healthy instances using an optimized “Artificial Neural Network”.

An enhanced method for premature lung cancer analysis utilizing image processing, deep learning, and metaheuristics was suggested in a recent work of Lu et al. (2021). They used the marine predator’s method to improve organization and network accuracy. On the “RIDER dataset”, the approach was assessed and contrasted with several pre-trained deep networks, such as “CNN ResNet-18”, “GoogLeNet”, “AlexNet”, and “VGG-19”. The outcomes distinctly showed that the proposed strategy performed better than the compared approaches, highlighting its superiority in lung cancer diagnosis.

3. PROPOSED METHODOLOGY

In this study, a COVID and Lung Cancer classification model is anticipated that encompasses four essential phases: “Preprocessing”, “Feature Extraction”, “Feature Selection”, and “Classification”. The approach is designed to leverage the capabilities of Computed Tomography (CT) imaging and Deep Learning (DL) features for accurate and effective classification. The initial phase involves preprocessing the lung CT images to enhance their quality and reduce noise. This prepares the images for subsequent analysis. At the next step, perform feature extraction to capture relevant information from the imageries, aiming to excerpt discriminative features that are indicative of lung cancer and COVID. To address the challenge of feature selection, introduce a “Novel Hybrid algorithm called GAO”. By combining the strengths of the “Genetic Algorithm (GA)” and “Arithmetric Optimization Algorithm (AOA)”, the selection of informative features is enhanced, leading to improved classification performance. Studies show that the suggested methodology is good at correctly diagnosing COVID and lung cancer. By automatically extracting relevant attributes and harnessing the power of deep learning techniques and meta-heuristics, our proposed approach offers a promising solution for the precise and efficient classification of lung cancer, contributing to improved cancer evaluation and treatment decision-making.

3.1 Preprocessing

Preprocessing is a critical stage in preparing medical images, including those related to lung cancer and COVID-19, for analysis and classification. Among the various preprocessing techniques available, the median filter is commonly employed to diminish distortion and improve image quality. (Ben Abdallah et al., 2018, 2016, 2014; Elfouly et al., 2021; Elshazly et al., 2013a; Kumar et al., 2015a). The median filter is a nonlinear cleaning method that replaces each pixel value with the median estimate of its neighboring pixels. It is particularly effective in mitigating salt-and-pepper noise, a common occurrence in medical images. Lung cancer and COVID-19 images often suffer from different types of noise, such as random noise and artifact noise. The median filter considerably decreases noise by substituting noisy color numbers with the neighborhood's average significance, producing smoother images with improved visual clarity. (Bouakrif et al., 2019; ElBedwehy et al., 2014; Inbarani et al., 2018; Kumar et al., 2017, Sundaram et al., 2021; Zhu & Azar, 2015). This technique effectively removes noise while preserving crucial image structures, ultimately improving the overall image quality and facilitating subsequent analysis and interpretation. Table 1 depicts the “Peak Signal Noise Ratio (PSNR)” and “Structure Similarity Index Method (SSIM)”, “Mean Square Error (MSE)”, “Features Similarity Index Matrix (FSIM)” for lung cancer and COVID datasets.

3.2 Materials

3.2.1 Dataset 1: Lung Cancer

For the analysis of the presented work, a set of CT scan pictures from an Iranian hospital are employed, with a particular emphasis on patients with lung cancer. This dataset includes images not only of lung cancer cases but also of individuals with COVID-19 and non-cancerous lung conditions. The images are divided into two classes: those with cancerous conditions, specifically lung cancer, and

Table 1. An overview of the various image quality metrics (PSNR, SSIM, MSE, FSIM)

Image	Metrics	Noisy Image	Gaussian Filter	Average Filter	Median Filter	Bilateral Filter
COVID	PSNR	31.9639	38.91708	33.15072	41.25209	39.41192
	SSIM	0.85376	0.97709	0.886055	0.98514	0.974788
	MSE	5.56987	6.109412	4.994891	4.56317	6.578923
	FSIM	0.96789	0.981478	0.962345	0.951236	0.997892
NON-COVID	PSNR	34.0622	40.5389	34.15142	45.71688	41.89566
	SSIM	0.93808	0.99193	0.948184	0.995581	0.988984
	MSE	5.11456	6.102356	8.75326	4.01253	5.01243
	FSIM	0.80563	0.872359	0.812369	0.80456	0.88123
LUNG CANCEROUS	PSNR	28.3965	32.1465	37.94561	43.2749	38.4871
	SSIM	0.84122	0.862145	0.901478	0.99531	0.93546
	MSE	4.75236	5.17563	4.12784	3.71881	5.23689
	FSIM	0.10098	0.10897	0.998963	0.99775	0.10236
NON-LUNG CANCEROUS	PSNR	32.1256	38.19745	37.25789	42.4267	40.51236
	SSIM	0.86974	0.945674	0.9312365	0.99553	0.951453
	MSE	5.50396	4.785121	3.962543	3.05903	4.912358
	FSIM	0.10523	0.10936	0.11235	0.99765	0.123478

those without cancerous conditions, which may depict various lung disorders such as COVID-19 and other abnormalities. In total, the dataset contains 364 CT scan images, with 238 images classified as cancerous (belonging to lung cancer patients) and 126 images categorized as non-cancerous, potentially representing lung disorders other than cancer, including COVID-19 (<https://data.mendeley.com/datasets/p2r42nm2ty/1>).

3.2.2 Dataset 2: COVID-19

COVID: The “COVID-CT” dataset is a valuable collection of Computed Tomography (CT) scan images specifically associated with COVID-19. This dataset was created by researchers at the “University of California, San Diego (UCSD)” to support advancements in COVID-19 research, particularly in the fields of “Deep Learning” and medical image analysis. It contains a whole of 349 CT scan images, with 349 cases representing patients diagnosed with COVID-19 and 397 cases representing individuals without COVID-19 (<https://github.com/UCSD-AI4H/COVID-CT>) (Nivetha et al., 2021).

4. FEATURE EXTRACTION USING CONVOLUTIONAL NEURAL NETWORK

CNN, a modification of the “Multi-Layer Perceptron (MLP)”, offers significant advantages in pattern recognition due to its ability to reduce data dimensionality, sequentially extract features, and perform classification. (Azar et al., 2020h; Aziz et al., 2013a; Barakat et al., 2020; Eid et al., 2013; El et al., 2021; Hassanien et al., 2014a). The inspiration for the basic architecture of CNN can be traced back to the visual cortex model proposed by “Hubel and Wiesel in 1962”. In 1980, “Fukushima introduced the Neocognitron”, which was the first implementation of CNN. Building upon Fukushima’s work, LeCun et al. achieved state-of-the-art performance in “pattern recognition” errands using the error gradient method in 1989.

The classical CNN architecture developed by “LeCun et al.” extends the traditional MLP and incorporates three key ideas: “local receptive fields”, “weight sharing”, and “spatial/temporal subsampling”. (Azar, 2013a,b; Aziz et al., 2012; Babajani et al., 2019; Banu et al., 2014; Dudekula et al., 2023; Elshazly et al., 2013b; Inbarani et al., 2022; Inbarani & Nivetha, 2021; Kumar et al., 2019). These concepts are ordered into dual forms of layers: “Convolution layers” and “subsampling layers”. The processing layers consist of “Convolution Layers (C1, C3, and C5)” interleaved with “subsampling layers (S2 and S4)”, followed by the “output layer (F6)”. These “Convolution and Subsampling layers” form feature maps and are organized in planes.

“Convolutional Neural Networks (CNNs)” have reformed the arena of “Computer Vision” by automatically learning and extracting meaningful features from images. CNNs excel at capturing high-level visual representations, making them ideal for tasks like image classification, object detection, and medical image analysis. CNNs leverage the concept of local receptive fields, where small filters scan the input image to capture local patterns and structures. (Aziz et al., 2013b; Banu et al., 2017; Ding et al., 2015; Elshazly et al., 2013c; Kumar et al., 2015b; Sayed et al., 2020; Samanta et al., 2018). As the information propagates through the network, deeper layers extract increasingly abstract and task-specific features. This hierarchical process allows CNNs to identify complex patterns, shapes, and textures that are crucial for distinguishing between different image classes or detecting specific objects.

4.1 Mathematical Model for CNN

CNNs undergo deuce foremost training phases: “feedforward” and “backpropagation”. In the feedforward stage, the accrual picture is processed by multiplying the input with neuron variables and applying a convolution operation in an apiece portion of the network. The resulting yield is then assessed. (Emary et al., 2014a; Hassanien et al., 2023, 2020, 2019a,b, 2014b; Inbarani et al., 2020; Sain et al., 2022; Santoro et al., 2013). During network learning, the objective is to minimize the fault between the network yield and the exact result, which is quantified by a loss function.

In the backpropagation phase, a technique called the backpropagation algorithm is applied based on the error value. This algorithm uses the chain rule to calculate the derivatives of the variables and updates them grounded on their impact on the network's fault estimate. This iterative process involves repeating the feedforward training multiple times to improve the network's training (Hashemi et al., 2013; Emary et al., 2014b; Humaidi et al., 2020a; Sallam et al., 2020; Sayed et al., 2019). The goal is to learn kernel matrices that capture meaningful features for image classification. The backpropagation algorithm optimizes the network's weights to find the optimal values. To perform the layer convolution, a sliding window is introduced, which applies the dot product operation with the weights. The “activation function” commonly used in CNNs is the “Rectified Linear Unit (ReLU)”, defined as follows:

$$f(x) = \max(x, 0) \quad (1)$$

Max pooling is utilized in CNNs to reduce the output scale and extract the most salient features. To optimize the neuron weights for better performance, the training pair error is computed (Firouz et al., 2015; Fati et al., 2022; Malek et al., 2015a Salam et al., 2022). The backpropagation technique minimizes the cross-entropy loss, which can be articulated as:

$$\sum_{cross} = \sum_{j=1}^N \sum_{i=1}^M -d_j^{(i)} \log y_j^{(i)} \quad (2)$$

Here, d_j characterizes the desired yield vector for the m^{th} class, and:

$$d_j = \left(0, \dots, 0, \underbrace{1, \dots, 1}_k, 0, \dots, 0 \right) \quad (3)$$

$y_j^{(i)}$ is obtained through the softmax function. The softmax function computes the possibility of partitioning over classes for a specified input sample (Fekik et al., 2018a; Jothi et al., 2019a; Ramadan et al., 2022; Salam et al., 2021):

$$y_j^{(i)} = \frac{e^{f_j}}{\sum_{i=1}^l e^{f_i}} \quad (4)$$

where ‘l’ signifies the “sample number”.

The endmost loss outcome includes an additional weight penalty term to regulate the magnitude of the weights. It can be represented as (Azar et al., 2020h; Fekik et al., 2018b; Humaidi et al., 2021; Pilla et al., 2021a):

$$L = \sum_{j=1}^N \sum_{i=1}^M -d_j^{(i)} \log y_j^{(i)} + \frac{1}{2} \rho \sum_K \sum_L W_{k,l}^2 \quad (5)$$

Here, ρ is the “weight penalty coefficient”, W_k denotes the “connection weight”, k in layer l, and the Layer l’s connections are represented by the letters L and K which stand for the total number of layers. Table 2 depicts the extraction of features in CNN architecture (Humaidi et al., 2020b; Kumar et al., 2014b, Pintea et al., 2018).

4.1.1 Description for Each Layer

1. **Conv2D Layer (32 filters, kernel size 3x3, ReLU activation):** This convolutional layer performs 2D convolution on the input image. It uses 32 filters to capture different image features and applies the Rectified Linear Unit (ReLU) activation function to introduce non-linearity.
2. **MaxPooling2D Layer (2x2 pool size):** This layer performs max pooling, which downsamples the input feature maps by taking the maximum value within each pooling region. It helps in reducing the spatial dimensions and capturing the most salient features.
3. **Conv2D Layer (64 filters, kernel size 3x3, ReLU activation):** Another convolutional layer is added to further extract higher-level features from the down-sampled feature maps.
4. **MaxPooling2D Layer (2x2 pool size):** Another max pooling layer is applied to down-sample the feature maps further.
5. **Flatten Layer:** This layer flattens the output from the previous layer into a 1-dimensional vector, preparing it for input to the fully connected layers.
6. **Dense Layer (128 units, ReLU activation):** This fully connected layer with 128 units applies the ReLU activation function to capture complex relationships between the extracted features.
7. **Dense Layer (100 units, softmax activation):** The final fully connected layer with 100 units applies the softmax activation function to generate class probabilities. This layer represents the output layer of the model.

The model is compiled with the Adam optimizer, categorical cross-entropy loss function, and accuracy as the metric for evaluation: Once the model is trained, the features are extracted using the model’s predicted, which takes the pre-processed input images as input and generates the corresponding feature vectors. The Total number of features extracted using CNN is 100 features.

4.2 Arithmetic Optimization Algorithm

Along with geometry, algebra, and analysis, arithmetic is one of the crucial elements of modern mathematics and a major part of number theory. The conventional computation methods typically used to examine numbers are known as arithmetic operators, such as “multiplication”, “division”,

Table 2. Description of the parameter settings used in CNN

Layer	Type	Filter Size	Number of Filters	Stride
Input	256*256*1			
Conv_1	CL+ReLU	3x3	32	1x1
MPL_1	ReLU	2x2		
Conv_2	CL+ReLU	3x3	64	1x1
MPL_2	ReLU	2x2		
Flatten				
Dense_1	ReLU		128	
Dense_2	Softmax		100	

“addition”, and “subtraction” (Abualigah et al., 2021; Fouad et al., 2021; Ganesan et al., 2022; Humaidi et al., 2023; Khettab et al., 2018; Pintea et al., 2021b). To choose the finest element among a group of candidate alternatives, employ these straightforward operators as mathematical optimization. Optimization issues arise in all quantitative fields, including operations research, engineering, economics, and computer science. Mathematicians have been fascinated by the development of solution approaches for decades. The procedure of arithmetic operators in resolving arithmetic problems is the primary source of inspiration for the proposed AOA. The behavior of arithmetic operators such as “multiplication”, “division”, “addition”, and “subtraction” is used in this research (Fredj et al., 2016; Jothi et al., 2013; Mukherjee et al., 2014 ; Malek et al., 2015b; Pilla et al., 2019, 2020).

The primary population in AOA is formed at random using the following equation:

$$x = LB + (U - L) \times \delta \quad (6)$$

where x stands for the population’s response. U and L stand for the higher and lesser bounds of the exploration space for an objective function. The arbitrary variable with an among [0, 1] is called δ (Azar et al., 2014b; Gharbia et al., 2014; Mustafa et al., 2020; Panda & Azar, 2021; Pilla et al., 2021b).

The choice of exploration and exploitation was made before the start of AOA based on the results of the “Math Optimizer Accelerated (MOA)” task, which is calculated using Eq. (2):

$$MOA(C_Iter) = Min + C_Iter \left(\frac{Max - Min}{M_Iter} \right) \quad (7)$$

where the functional result at the t^{th} iteration is represented by MOA (C_Iter). C_Iter indicates the repetition that is currently running between 1 to the most iterations possible (M_Iter). The notation Min and the notation Max are used to indicate the lowest and extreme estimates of the MOA, respectively.

In AOA, the “exploration” or global search has been carried out utilizing search techniques based on the “Division (D)” and “Multiplication (M)” operators, which are expressed as Eq. (3), (Azar et al., 2013a):

$$x_{i,j}(t+1) = \begin{cases} best(x_j) \div (MoPr + \epsilon) \times ((U_j - L_j) \times \mu + L_j), & \text{rand2} < 0.5 \\ best(x_j) \times (MoPr) \times ((U_j - L_j) \times \mu + L_j), & \text{otherwise} \end{cases} \quad (8)$$

where $x_{i,j}(t)$ denotes the “ j^{th} ” place of “ i^{th} ” person in the current generation and $x_i(t+1)$ denotes the “ i^{th} ” solution of the “ $(t+1)^{\text{th}}$ ” iteration, $best(x_j)$ denotes the “ j^{th} ” place of the present finest answer. ϵ is a very small positive integer, and U_j, L_j stands in for the higher and lesser limits of the “ j^{th} ” location, respectively, “ μ ” a controlling constraint. The following formula has been used to calculate the “Math Optimizer Probability (MoPr)”, which is a constant:

$$MoPr(t) = 1 - \frac{t^{\frac{1}{\theta}}}{M_Iter^{\frac{1}{\theta}}} \quad (9)$$

where $MoPr(t)$ represents the $MoPr$ function's value at the t^{th} iteration. The extreme number of repetitions is M_{Iter} . is a crucial variable that governs the effectiveness of the extraction process during all iterations (Azar et al., 2022c; Jothi et al., 2022; Humaidi et al., 2021; Nasser et al., 2021; Mathiyazhagan et al., 2022; Mohanty et al., 2021)

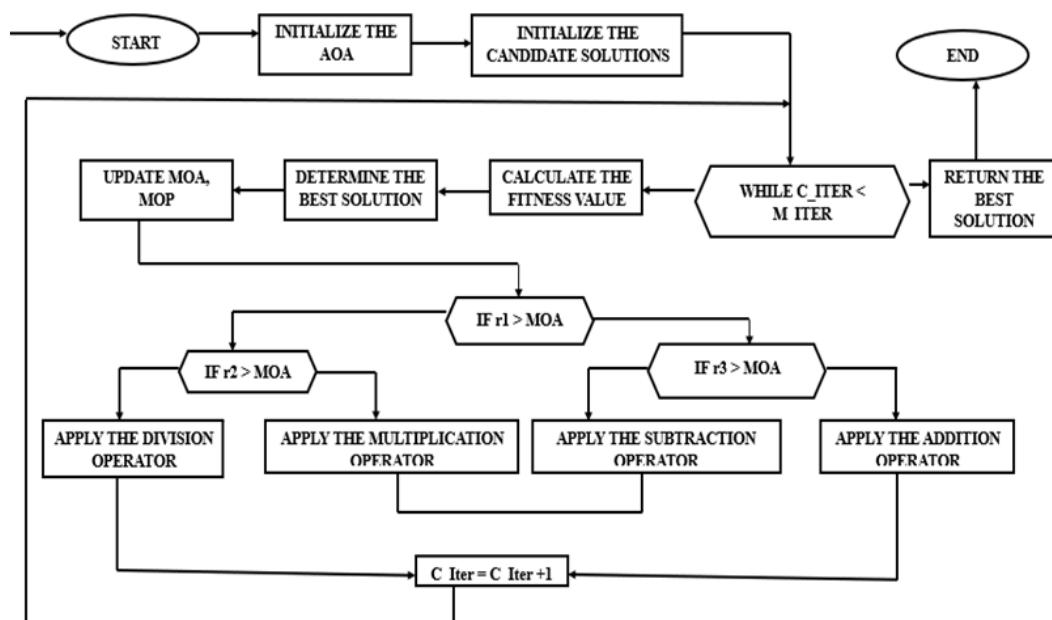

The “exploitation strategy” within the context of AOA has been devised through the utilization of the “Subtraction (S)” or “Addition (A)” operators, as articulated in Equation (5). This strategy is both continuous and static in nature. The process of AOA is delineated in Algorithm 1, aligning with the proposed approach to “exploration” and “exploitation.” The visual representation of the AOA procedure can be found in Figure 1, (Abualigah et al., 2021; Azar et al., 2013b; Ibraheem et al., 2020b; Jothi et al., 2019b; Kamal et al., 2020; Lavanya et al., 2022; Giove et al., 2013):

$$x_{i,j}(t+1) = \begin{cases} best(x_j) - (MoPr) \times ((U_j - L_j) \times \mu + L_j), & \text{rand3} < 0.5 \\ best(x_j) \times (MoPr) \times ((U_j - L_j) \times \mu + L_j), & \text{otherwise} \end{cases} \quad (10)$$

4.3 Genetic Algorithm

The “Genetic Algorithm” is a meta-heuristic that draws inspiration from the evolution method and is a member of the broad class of “Evolutionary Algorithms” used in computing and informatics. By concentrating on bio-inspired operators like “Selection”, “Convergence”, or “Mutations”, these procedures are widely employed to produce superior results to optimization and exploration challenges (Azar et al., 2014a; Najm et al., 2020; Gorripotu et al., 2019). In 1988, John Holland, the author, created GAs based on “Darwin’s evolutionary theory”. He subsequently enlarged the GA in 1992. The category of evolutionary algorithms includes this algorithm. The employment of evolutionary algorithms allows for the solving of issues for which there is not yet a clear-cut, effective solution. This method is utilized in modeling and simulation where arbitrariness function is applied, as well

Figure 1. Flowchart representation for AOA algorithm (Abualigah et al., 2021)

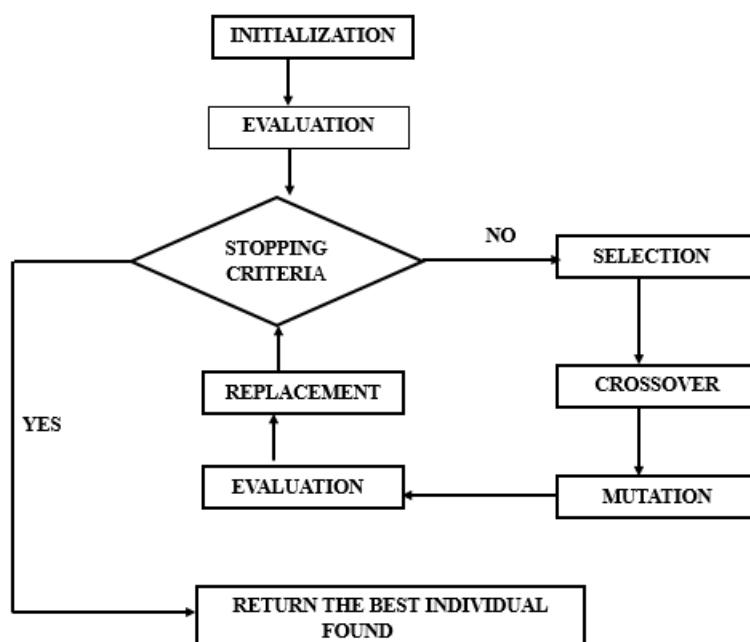

as to do optimization difficulties (“Scheduling”, “Shortest Path”, etc.) GA is key to the population of the intrant for the problem of optimizing that is developed in the direction of better options (known as individuals, animals, or genotypes) (Holland et al., 1992). Each candidate’s result takes a set of traits (the genes or phenotype) that can be altered and evolved; results are commonly represented as cords of 0s and 1s in binary digits, though alternative codecs are permitted. (Azar & Hassanien, 2015; Ibrahim et al., 2020; Khamis et al., 2021; Khan et al., 2021; Malek & Azar, 2016a). The population is thought of as a mechanism of generation for each reproduction in evolution, which often begins with a community of randomly selected people. The population’s overall fitness is assessed for each generation. The value of the objective feature being resolved, however, is typically what determines fitness. When the gene is changed to produce a novel peer group series for everyone (recombined and perhaps altered arbitrarily), suitably fit entities are probabilistically particular from the current population. Over the next generation of the process, newer candidate strategies would be used. The algorithm often comes to an end after a predetermined number of generations or after enough satisfaction has been produced. (Azar et al., 2012; Inbarani et al., 2014b; Khamis et al., 2022; Liu et al., 2022). As a result, each new generation is better suited to the surroundings of the population. Figure 2 depicts the flowchart for AOA as follows,

4.4 Proposed Novel Hybrid Genetic Arithmetic Optimization (NHGAO)

The Hybrid Genetic Algorithm with Arithmetic Optimization is a combination of two powerful optimization techniques: Genetic Algorithm (GA) and Arithmetic Optimization (AO). By leveraging the strengths of both approaches, this hybrid algorithm aims to overcome its limitations and achieve improved optimization performance. (Azar & Vaidyanathan, 2015a, b; Khamis et al., 2021 Liu et al., 2020; Meghni et al., 2017b).

“Genetic Algorithm” is a “population-based search algorithm” inspired by the principles of “natural selection” and “genetics”. It utilizes genetic operators, such as “selection”, “crossover”,

Figure 2. Flowchart representation for GA algorithm (Holland, 1992)

and “mutation”, to discover the solution space and evolve toward better solutions. GA is actual in exploring an extensive choice of solutions and maintaining population diversity, allowing it to handle complex optimization problems with large solution spaces. However, it may struggle with fine-tuning individual solutions and getting trapped in local optima.

Arithmetic Optimization is an arithmetic-based optimization technique that focuses on refining individual solutions through arithmetic operations (Azar et al., 2020e; Malek & Azar, 2016b). It operates on a single solution and makes small adjustments using operations like addition, subtraction, multiplication, and division. AO excels in local search and fine-tuning solutions, enabling it to converge faster and achieve higher solution quality. However, it may suffer from limited exploration capability and difficulties in escaping local optima.

The hybridization of GA and AO addresses these limitations by synergistically combining their strengths. The algorithm starts with a primary population generated by GA, which explores the solution space and maintains diversity. The population then undergoes AO to refine individual solutions using arithmetic operations. This hybrid approach allows for efficient exploration of the solution space by GA, while AO provides fine-grained adjustments and exploitation of promising solutions. The advantages of the Hybrid Genetic Algorithm with Arithmetic Optimization include enhanced exploration and exploitation, improved solution quality, efficient local search, and flexible adaptation. By leveraging the exploration capabilities of GA and the refinement abilities of AO, the hybrid procedure strikes a equilibrium among “exploration and exploitation”, leading to better convergence and solution quality. Additionally, the algorithm can be tailored to adapt the balance between GA and AO based on the problem characteristics, making it a versatile optimization approach.

Overall, the hybridization of GA and AO offers a powerful optimization framework that combines the strengths of both algorithms, allowing for efficient exploration, fine-tuning of solutions, and improved optimization performance. It is predominantly well-matched for explaining multipart optimization problems where a steadiness among “exploration and exploitation” is crucial. Table 3 shows the parameter settings for the Proposed NHGAO. Figure 3, 4 and 5 depict the pseudocode for the AOA, GA, and the proposed NHGAO.

5. HYPERPARAMETER TUNING FOR GA, AOA, AND NHGAO

For the NHGAO (Novel Hybrid Genetic Arithmetic Optimisation Algorithm) to maximize the recital of the hybrid algorithm and produce superior fallouts, hyperparameter adjustment is a crucial step. Hyperparameters are parameters that are set before training but are not learned during training. (Azar, 2013d; Azar et al., 2017) They take a substantial influence on the algorithm’s performance and behavior as well as the outcome. Hyperparameter tuning involves finding the finest amalgamation of hyperparameter values for both the arithmetic optimization and genetic algorithm components. These hyperparameters include population size, maximum iterations, and the omega value, which controls the balance between exploration and exploitation.

Proper hyperparameter tuning ensures that the algorithm efficiently discovers the resulting space, congregates to optimal or near-optimal solutions, and achieves improved accuracy and classification results. The outcomes of the “Genetic Algorithm”, “Arithmetic Optimization Algorithm”, and “Novel Hybrid Genetic-Arithmetic Optimization Algorithm” are displayed in Tables 4,5, and 6. It is vibrant that the presented method produces the finest outcomes.

5.1 Case Study and Interpretations

5.1.1 Case 1

Novel Hybrid Genetic Arithmetic Optimization algorithm has been anticipated to address to progress the execution of the optimization progression. Statistical techniques are used to analyze and compare

Table 3. Parameter settings for Proposed NHGAO

Parameter Description for NHGAO	
Problem Formulation	The optimization problem being solved in the given code is feature selection for a classification task.
Initialization	Set the parameters for both GA and AO, such as the “population size”, “mutation rate”, and “maximum number of iterations”.
Initial Population	Generate an initial population of individuals using GA techniques. A piece distinct epitomizes a possible result of the optimization problem. The population is usually created randomly or based on specific initialization strategies.
GA Phase	Apply GA operators, including “Selection”, “Crossover”, and “Mutation”, to evolve the population and explore the solution space. Selection ensures that fitter individuals have a higher chance of being chosen for reproduction, while crossover combines the genetic material of selected individuals to generate offspring. Mutation introduces small random changes to maintain diversity and avoid premature convergence.
AO Phase	Apply AO techniques to refine the selected individuals from the GA phase. AO employs arithmetic operations, such as “Addition”, “Subtraction”, “Multiplication”, and “Division”, to modify the solutions and improve their fitness values. This phase aims to fine-tune the solutions obtained from the GA phase and enhance their quality.
Hybridization of GA and AO Phase	Integrate the GA and AO phases by combining the selected individuals from GA with the mutated individuals from AO. This integration can be performed through various strategies, such as incorporating AO as a local search operator within the GA framework.
Fitness Function	The fitness metric used is the accuracy score. The accuracy score is a commonly used evaluation metric for classification problems. The accuracy score quantifies the ratio of correctly classified instances to the total number of instances in the dataset.
Optimization Function	To maximize the accuracy of a Random Forest Classifier on a given dataset.
Constraint	The constraint limits the maximum number of selected features. This constraint ensures that the model does not select an excessively large number of features, which can lead to overfitting or increased computational complexity.
Selection and Replacement	Select the best individuals grounded on their “fitness values”. The fittest individuals are preserved, while the fewer fit individuals are replaced with the offspring generated through GA and AO operations. This selection process helps improve the population’s overall fitness and drives the optimization process toward better solutions.
Termination Criterion	Determine the ending condition for the hybrid algorithm. This could be reaching a maximum number of iterations, convergence of the objective function, or achieving a preset fitness threshold. The termination criterion ensures that the algorithm stops when it has achieved satisfactory results or when further iterations are unlikely to yield significant improvements.

the execution of three algorithms that have been employed using test algorithms of 50, 500, and 1000 Iterations respectively. In the study, each algorithm is separately running up to 50,100,1000 times. Except for the suggested algorithm, the control parameters for the search algorithms are taken from (Arabali et al., 2012, Guo et al., 2008). This ensures a fair comparison when carrying out assessments of related functions.

5.1.2 Case 2

It is well known that in metaheuristics-based optimization-based algorithms, a rise in the “population” and “the number of iterations” causes an increase in the length of time the algorithms take to complete. As a result, in the current study, the algorithm’s maximum iterations are 50, 100, and 1000.

Figure 3. Pseudocode for Arithmetic Optimization Algorithm

INPUT: n: Number of variables, f: Objective function, N: Population size, T: Maximum number of iterations, μ: Mutation probability, ρ: Crossover probability OUTPUT: Selected features: array of selected features with values of 0 or 1, Accuracy: the accuracy of the selected feature subset
<pre> 1. START 2. INITIAL Population P = randomly initialize n solutions of size n using Equation 1 3. EVALUATE the fitness of each solution and save the best one 4. SET T = 1 5. While t <= T do: 6. While stopping condition is not met, do the following: 7. a. EVALUATE fitness values for each solution position. 8. b. KEEP TRACK of the best solution found so far. 9. c. UPDATE the MoAc value using Equation (2). 10. d. UPDATE the MoPr value using Equation (4). 11. FOR EACH solution i, do the following: 12. FOR EACH SOLUTION j, do the following: 13. GENERATE three random values random1, random2, and random3 between 0 and 1. 14. IF (random1 is > MoAc): 15. BEGIN EXPLORATION 16. IF (random2 is > 0.5): 17. UTILIZE the Division operator - D "/" 18. UPDATE the ith solution's positions using the first rule of Equation (3). 19. ELSE: 20. UTILIZE the Multiplication operator - M "x" 21. UPDATE the ith solution's positions using the second rule of Equation (3). 22. ENDIF 23. ELSE: 24. BEGIN EXPLOITATION 25. IF (random3 is > 0.5): 26. UTILIZE the Subtraction operator (S "-") 27. UPDATE the ith solution's positions using the first rule of Equation (5). 28. ELSE: 29. UTILIZE the Addition operator (A "+") 30. UPDATE the ith solution's positions using the second rule of Equation (5). 31. END IF 32. END FOR 33. END FOR 34. END WHILE 35. RETURN the best global solution found. 36. END </pre>

5.1.3 Case 3

The performance of all algorithms is quantitatively evaluated. The proposed method is contrasted with the outcomes that were obtained. The effectiveness of the computer hardware configuration, the design of the algorithm, and the metaheuristic optimization technique all influence computation times. The ANACONDA software, which is installed on a computer with an i5-10210U CPU processor successively at a processing speed of 2.11 GHz and 8 GB of RAM, is utilized to run the analyses as part of the scope of the study.

5.1.4 Case 4

The hyperparameter tuning process involved exploring and comparing different settings for population size, maximum iterations, and the omega value to develop the execution of the algorithms. The population size embodies the numeral of entities in the population. The genetic algorithm and arithmetic optimization utilized a population size of 100, allowing for a diverse set of solutions to be evaluated. In contrast, the hybrid algorithm employed a smaller population size of 50. Despite this reduction, the hybrid algorithm demonstrated its efficiency by achieving a comparable accuracy of 0.98. This suggests that the hybrid algorithm be situated to find optimal solutions using a more focused and compact population.

Figure 4. Pseudocode for Genetic Algorithm

INPUT: n -Number of individuals in the Population, γ - Fraction of the population to be replaced by crossover in each iteration, μ - Mutation Rate (GA (n, γ , μ))
OUTPUT: Selected features: Selected features Accuracy: the accuracy of the selected feature subset
<pre> 1. START 2. INITIALISE Generation 0; 3. k := 0; 4. P_k := a population of n randomly-generated individuals; 5. EVALUATE P_k: 6. COMPUTE fitness(i) for each $i \in P_k$ 7. do 8. { 9. CREATE GENERATION k + 1: 10. SELECT $(1 - \gamma) \times n$ members of P_k and insert into P_{k+1} 11. SELECT $\gamma \times n$ members of P_k; pair them up; produce offspring; insert the offspring into P_{k+1} 12. SELECT $\mu \times n$ members of P_{k+1} invert a randomly-selected bit in each; 13. EVALUATE P_{k+1}: 14. COMPUTE fitness(i) for each $i \in P_{k+1}$ 15. INCREMENT: 16. k := k + 1; 17. } 18. WHILE Fitness of fittest individual in P_k is not high enough; 19. RETURN the fittest individual from P_k 20. END </pre>

Figure 5. Pseudocode for Novel Hybrid Genetic Arithmetic Optimization (NHGAO)

INPUT : Population size, Mutation rate, Generations OUTPUT : Selected features: Selected features Accuracy: the accuracy of the selected feature subset
<pre> 1. START 2. GENERATE AN INITIAL POPULATION OF INDIVIDUALS 3. DEFINE the fitness function (f) 4. EVALUATE the fitness of an individual 5. CALCULATE The accuracy. 6. DEFINE the mutate function 7. DEFINE THE ARITHMETIC OPTIMIZATION 8. DEFINE GENETIC ALGORITHM WITH ARITHMETIC OPTIMIZATION 9. INITIALIZE the population 10. REPEAT FOR a specified number of generations: a. APPLY arithmetic optimization to each individual in the population b. EVALUATE the fitness of each individual in the population. c. SELECT parents for crossover based on fitness using selection mechanisms. d. PERFORM crossover and mutation to create new offspring. e. REPLACE the worst individual in the population with the offspring. 11. RETURN the best individual and its fitness value from the final generation. 12. USE the genetic algorithm with arithmetic optimization function to obtain the best individual and its fitness value. 13. RETURN best individual and its fitness value. 14. END </pre>

5.1.5 Case 5

The maximum iterations parameter determines “the numeral of reiterations” or generations the algorithm goes through. The “genetic algorithm” had a maximum iteration of 50, while both the arithmetic optimization and hybrid algorithm utilized 500 iterations. Surprisingly, the genetic algorithm achieved an accuracy of 0.94, indicating its effectiveness in producing accurate results within a slighter numeral of repetitions. On the other point, the longer iterations in the arithmetic optimization and hybrid algorithm allowed for a more extensive search of the solution space, potentially leading to improved accuracy.

5.1.6 Case 6

The omega value is a crucial parameter that restraint the stability amid “exploration and exploitation” in the algorithms. The genetic algorithm had an omega value of 0.9, emphasizing exploration to discover diverse solutions. The arithmetic optimization employed an omega value of 0.5, striking a

firmness among “exploration and exploitation”. In contrast, the hybrid procedure utilized an omega value of 0.1, prioritizing exploitation to exploit the discovered promising regions. These distinct omega values influenced the algorithm’s search behavior, enabling the genetic algorithm to explore a varied choice of solutions, the arithmetic optimization to sustain a trade-off amid “exploration and exploitation”, and the hybrid algorithm to exploit promising areas for optimal solutions.

5.1.7 Case 7

By carefully tuning these hyperparameters, the hybrid algorithm achieved the highest accuracy of 0.98, surpassing the genetic algorithm’s accuracy of 0.94 and the arithmetic optimization’s accuracy of 0.93. The hybrid algorithm’s success can be attributed to its ability to intelligently balance the exploration and exploitation trade-off, effectively utilizing a smaller population size to find optimal solutions. This demonstrates the algorithm’s capability to adaptively adjust its search strategy based on the problem requirements and improve accuracy through a combination of exploration and exploitation.

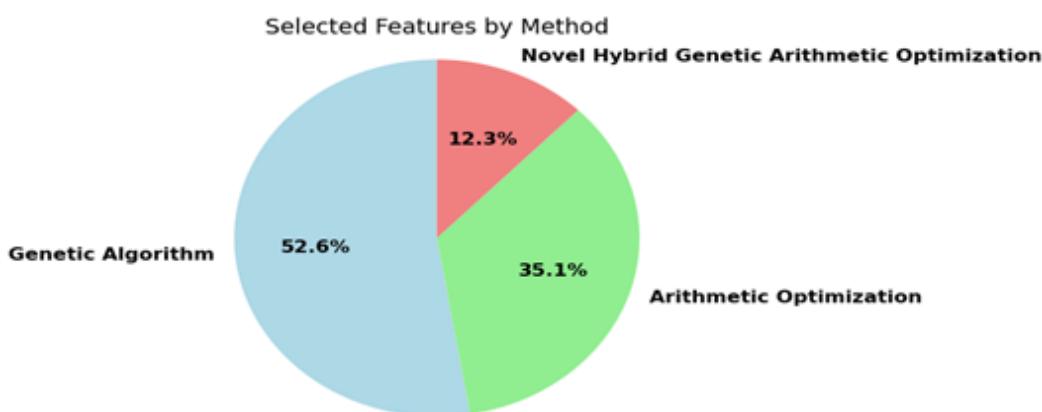

6. EXPERIMENTAL ANALYSIS

6.1 Effectiveness of the Proposed Features Selection Technique

The presented approach is used to reduce the measurement of two datasets, Lung cancer, and COVID datasets using feature selection methods. K-fold cross-validation was used for better evaluation of test results to avoid overfitting difficulties throughout the preparation and testing processes. (Azar et al., 2016b). For processing the effectiveness of the presented supervised feature selection strategy, three different meta-heuristic optimization techniques are used. They are “Genetic Algorithm”, “Arithmetic Optimization Algorithm” and “Proposed Novel Hybrid Genetic Arithmetic Optimization Algorithm”.

The efficiency of the feature selection techniques in percentage is seen in Figure 6. The “Genetic Algorithm” and “Arithmetic Optimization Algorithm” algorithms are contrasted with the proposed Novel Hybrid Genetic Arithmetic Optimization approach in this diagram. The light blue color depicts the selected features of the Genetic Algorithm as 52.6%. Similarly, to this, the Arithmetic Optimization based algorithm reduced the features by 35.1%, and the light pink color depicts the proposed method which reduced the features by 12.3%. It’s believed that the irrelevant features are reduced by using the proposed system Novel Hybrid Genetic Arithmetic Optimization algorithm.

Figure 6. Reduction percentage for various algorithms and Proposed Novel Hybrid Genetic Arithmetic Optimization (NHGAO)

6.2 Assessment of the Classification Performance

To determine the usefulness of the classifiers, a variety of performance metrics were used to evaluate them. The datasets were divided into training (70% of samples) and testing (30% of samples) sets and the selected features were fed into the classifiers. Ten-fold cross-validation was used to verify the classification results. Although accuracy is a frequently used evaluation metric in traditional applications, it might not be appropriate for evaluating a dataset of skewed images (Nivetha & Inbarani, 2022a). When class distributions are extremely skewed, it is common for there to be no classification rules developed for the minority class. Additional evaluation metrics were used in this work to solve this restriction. The efficacy of the classifier is evaluated using a combination of performance criteria, including “Precision”, “Recall”, “F1-score”, “Accuracy”, “Sensitivity”, “Specificity”, “G-Mean”, “Mathew Correlation Coefficient (MCC)”, “Lift”, “Youden’s index”, “Balance Classification Rate (BCR)”, “Computation Time” (Nivetha & Inbarani, 2022b). Table 7 shows the number of features acquired from the lung dataset and the COVID dataset.

6.4 Result and Discussion

The experiments were conducted on an Intel Core i5 processor with a maximum memory capacity of 2 GB. The feature selection algorithms were implemented in ANACONDA. The measurement equations can be described as follows, (Nivetha et al., 2022c):

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (11)$$

$$\text{Sensitivity} = \frac{TP}{TP + FP} \quad (12)$$

that using the NHGAO, AOA, GA, and Unreduced data approaches in comparison to the unreduced information increases the accuracy of order classification.

Tables 8 depicts the results of Genetic Algorithm, and Arithmetic Optimisation and other approaches for Unreduced Data. The evaluation results demonstrate the effectiveness of the proposed Novel Hybrid Genetic Algorithm-Arithmetic Optimisation algorithm. The innovative hybrid method demonstrates its superiority in effectively capturing both positive and negative examples, ultimately resulting in a significantly lower mistake rate, with consistently higher precision, recall, specificity, G-mean, MCC, Youden's Index, BCR, ROC area, and accuracy. This performance highlights the method's potential to provide predictions that are more trustworthy and balanced for improving classification outcomes.

Table 9 shows the results of Genetic Algorithm, Arithmetic Optimisation, and Novel Hybrid Genetic Arithmetic Optimisation technique for Unreduced Data. Notably, the Novel Hybrid Genetic Arithmetic Optimisation algorithm demonstrates outstanding precision, reaching 0.95, confirming its accuracy in anticipating positive situations. This precision is balanced, demonstrating its ability to make accurate positive and negative predictions with strong recall, F1-score, sensitivity, and specificity. The MCC score of 0.94 is impressive and indicates high overall classification quality. Notably, this strategy only slightly outperforms random guessing, as evidenced by the Lift score, which is significantly lower than that of the other methodologies. The Novel Hybrid Genetic Arithmetic Optimisation approach, however, consistently displays strong performance across a variety of measures, contributing to its noteworthy ROC area of 0.92 and a high accuracy of 0.95, positioning it as a robust choice for accurate and balanced classification.

The performance of the approaches can be determined by comparing the evaluation metrics of Genetic Algorithm, Arithmetic Optimisation, and Novel Hybrid Genetic Arithmetic Optimisation for Unreduced Data in Table 10. With balanced precision, recall, F1-score, sensitivity, and specificity, the Novel Hybrid Genetic Arithmetic Optimisation stands out as a top performer, demonstrating its effectiveness in both positive and negative predictions. The fact that it earns the highest G-mean (0.95) and BCR (0.96) scores stands up as evidence of its thorough class capture. It is exceptional in terms of overall categorization quality with a strong MCC score of 0.91. Additionally, this method exhibits reliability and potent discriminative power by maintaining competitive error rates and a strong ROC area (0.40 and 0.90, respectively).

Table 11 describes the balanced performance with good precision, recall, F1-score, and specificity when approaches Genetic Algorithm, Arithmetic Optimization, and Novel Hybrid Genetic Arithmetic Optimisation are compared for Unreduced Data. It continues to have competitive G-mean and MCC scores, demonstrating its propensity for prediction. This technique demonstrates its ability to provide

a thorough classification by performing particularly well in Youden's Index, BCR, and BER. Its reliability is further supported by precision and a strong ROC area, making it an appealing option for precise, comprehensive forecasts.

With a high score of 0.94, the Novel Hybrid Genetic Arithmetic Optimisation algorithm excels in terms of accuracy, indicating that it makes correct predictions for all classes. It has the lowest error rate, 0.06, demonstrating successful misclassification reduction. This high accuracy is consistent with consistently great performance on numerous metrics. The Unreduced Data technique, on the other hand, has the highest error rate (0.60), which denotes a higher percentage of inaccurate predictions. The Novel Hybrid Genetic Arithmetic Optimisation stands out as a reliable option for accurate forecasts with low error rates in terms of both accuracy and error rate as shown in Table 12.

Comparing the presented method to existing supervised feature selection techniques, the presented approach produces the lowermost bit classification and fault value. When related to alternative FS techniques, it is found that the NHGAO-based relative reduct algorithm creates the least amount of execution time.

Figures 7, 8, 9, 10, and 11 classification comparison for “accuracy”, “precision”, “recall”, and “F1-Score” for five classifiers such as “Decision Tree”, “Random Forest Classifier”, “Naïve Bayes

Figure 7. Classification accuracy for Decision Tree Classifier

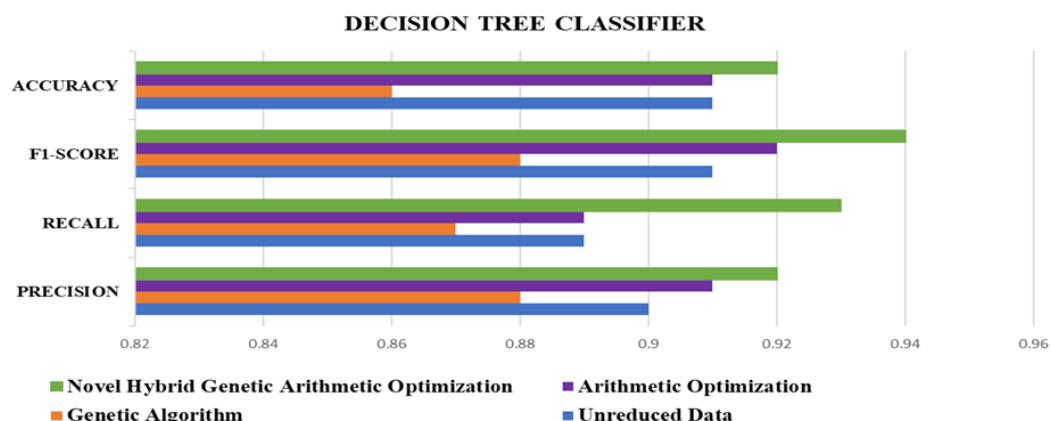

Figure 8. Classification accuracy for Random Forest Classifier

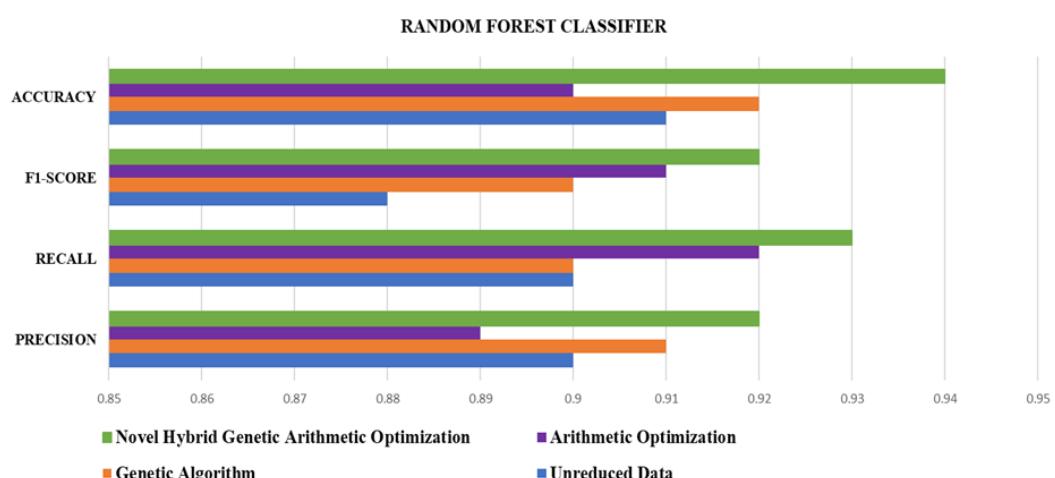

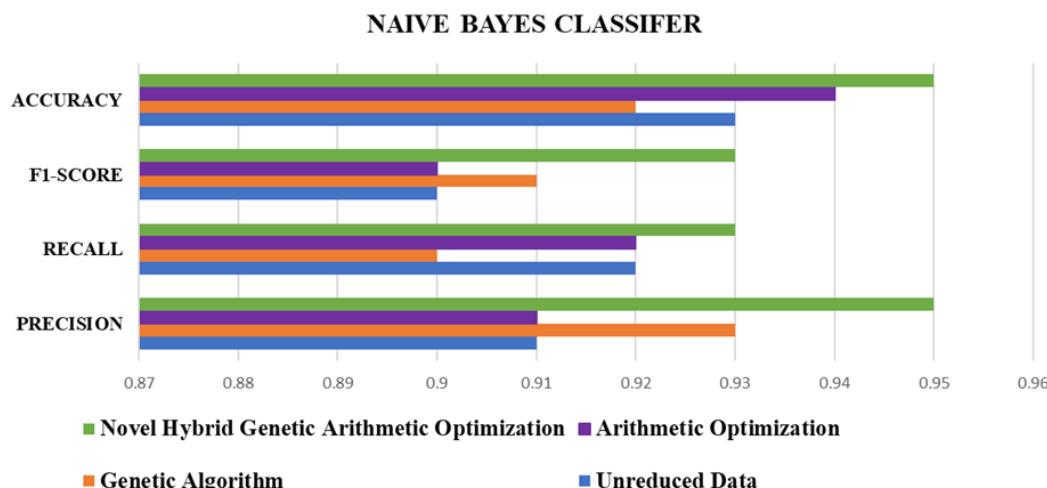

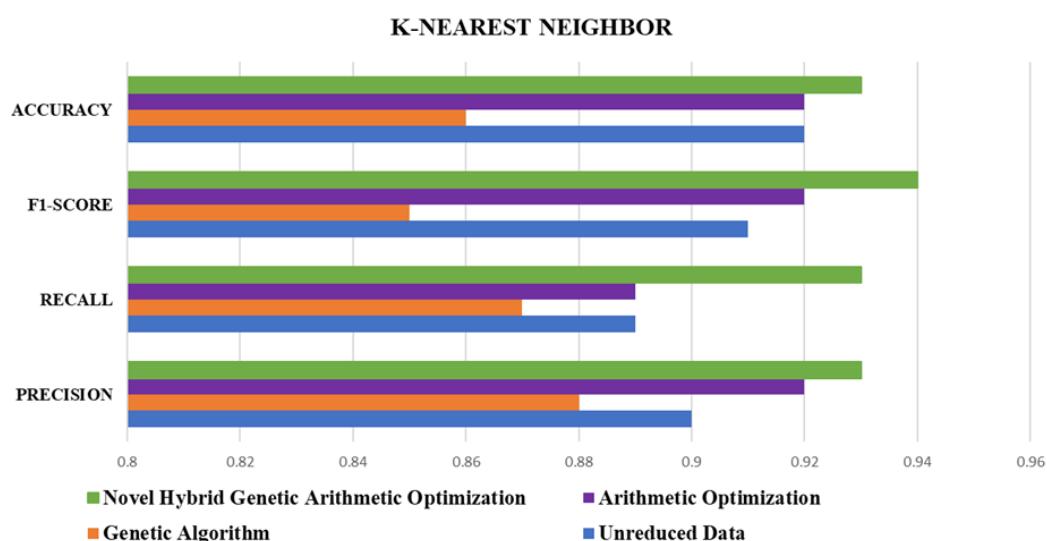

Figure 9. Classification accuracy for Naïve Bayes Classifier**Figure 10. Classification accuracy for KNN classifier**

Classifier”, “KNN Classifier” and “SVM classifiers”. A great tool for organizing, visualizing, and choosing classifiers based on performance is the ROC plot. (Nivetha & Inbarani, 2023a; Azar et al., 2016a). The idea of a “separator” variable is the foundation of the ROC curve. If the “criterion” or “cut-off” for positivity on the decision axis is altered, the frequency of positive and negative diagnostic test findings will change. The decision scale is only “implicit” when a diagnostic system’s results are evaluated based on subjective assessment. (Nivetha & Inbarani, 2023b; Azar et al., 2007), Such a variable is frequently referred to as a “latent” or unobservable variable. A ROC curve, also known as a curve in the unit square, is produced by plotting TPF (sensitivity) versus FPF (1-specificity) across various cut-offs has been represented in medical diagnosis (Azar et al., 2020c).

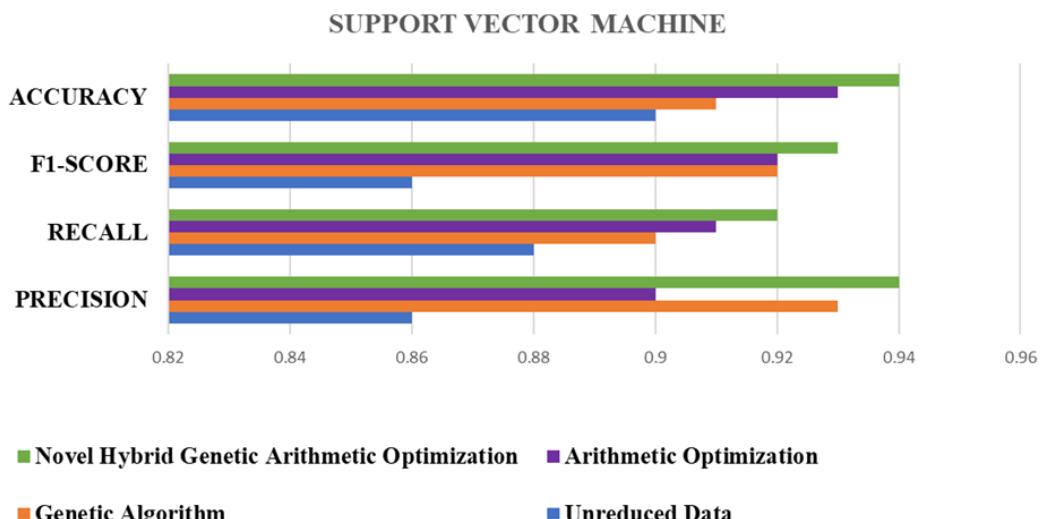

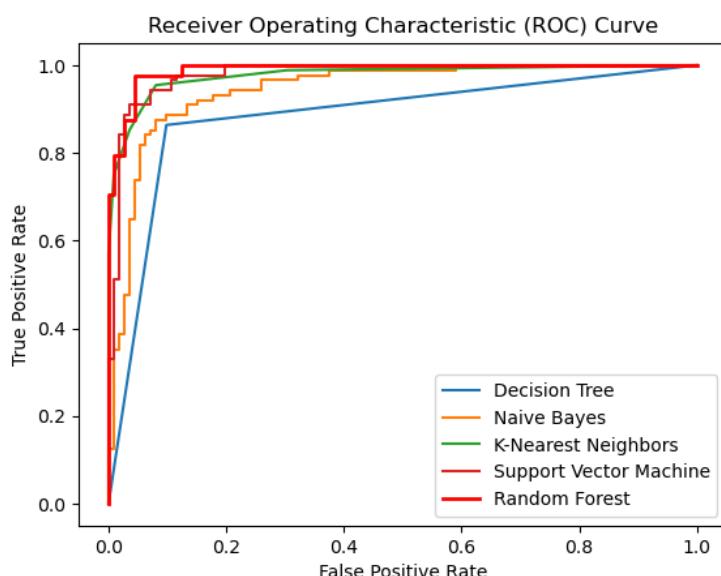

Figure 11. Classification accuracy for SVM classifier

Figure 12 displays the ROC plots for each classifier on the three datasets, utilizing the proposed NHGAO algorithm. The classification accuracy rates of the five classifiers differ from each other. (Nivetha et al., 2023a,b,c). Particularly, the “Random Forest classifier” outperforms the other classifiers, achieving the highest classification accuracy of 0.95%, as indicated by its position above the diagonal line in the graph. This result highlights the superior performance of the “Random Forest classifier” compared to the others in the classification task.

Figure 12. ROC plot for different classifiers for the proposed NHGAO selected features

7. CONCLUSION AND FUTURE DIRECTIONS

This research work addresses the complex challenge of feature selection in “Medical Image Processing”. This study introduced the innovative Novel Hybrid Genetic Arithmetic Optimization algorithm for feature selection. This approach, designed for feature selection and classification tasks using COVID and lung imaging datasets, merges genetic algorithm and arithmetic optimization to efficiently optimize feature subsets. The assessment of feature subset quality, guided by accuracy findings and employing the Random Forest classifier as a fitness function, underscores GA-AOA’s superiority over traditional genetic algorithms and arithmetic optimization. Novel Hybrid GAO excels in multiple performance metrics, encompassing “Accuracy,” “Precision,” “Recall,” “F1-Score,” “MCC,” “Sensitivity,” “Specificity,” “Geometric Mean,” “Lift,” and “Youden’s Index”. Notably, the hybrid algorithm achieves remarkable accuracy in classifying COVID and lung images, underscoring its effectiveness in both feature selection and classification tasks. The findings indicate that each applied metaheuristic optimization strategy substantially enhancing classification accuracy while concurrently reducing feature size. Comparative analyses against genetic algorithms and arithmetic optimization underscores the hybrid algorithm’s advantages, achieving superior accuracy with a reduced population size and fewer iterations. This study’s outcomes pave the way for potential expansions utilizing evolutionary algorithm-driven feature selection methods like Particle Swarm Optimization, Ant Colony Optimization etc., Moreover, the framework’s versatility positions it for application across various medical disciplines beyond the current scope of research.

ACKNOWLEDGMENT

The authors express their gratitude to the UGC-Special Assistance Programme for providing financial support for their research under the UGC-SAP at the level of DRS-II (Ref. No: F.5-6/2018/DRS-II(SAP-II), 26 July 2018) in the Department of Computer Science, Periyar University, Salem, Tamil Nadu, India.
