

Preface

Knowledge is traditionally compartmentalized into disciplines – a neat idea for categorization of knowledge but not without issue. Debate about discipline borders and the nature of disciplines has ensued for as long as disciplines have existed. Consequently, disciplines today are the result of substantial evolution (Osborne, 2015). That the term “disciplinarity” has had a host of prefixes—inter, intra, cross, anti, etc.—evidences the problematic nature of knowledge production and the idea of disciplines (Osborne, 2015).

Configuring knowledge into disciplines is useful for giving structure to knowledge, but it also oversimplifies our understanding of knowledge production. Importantly, organizing knowledge into disciplines induces a degree of fragmentation, which constrains the usefulness of knowledge. This is especially true in the application of knowledge to solve complex problems, and the present society is characterized by increasing levels of complexity. The past half a century set the stage for unprecedented rapid growth in knowledge and technical advancement. The cost of progress though, is greater complexity. Complexity can be thought of in terms of large, open systems characterized by nonlinear connectivity and interactivity, unpredictability, instability and disequilibrium producing a state of perpetual change (Rzevski, 2015). Largely driven by technological development, complexity is now a defining feature of the twenty-first century, and likely a defining feature of the future. Climate change, sustainability, unstable globalized economies, ethics in bio-technological development, and social disturbances to name just a few of the highly complex, ill-defined problems the human race is facing.

Complexity is disruptive. Established systems and processes become less effective or completely ineffective (Rzevski, 2015). The complex problems emanating from complex systems require new approaches and new methods of knowledge production. Against this context, it is unsurprising that the last few decades have seen acceleration in the debate around how human knowledge is to be organized.

There has also been significant investment in developing our understanding of knowledge production. Problems now are many orders of magnitude more complex than many of those in the past. Established ways of knowing are disrupted, and the knowledge economy is in full swing. Amid the debate, one emerging view is that attempting to address such problems requires the transcendence of disciplinary boundaries, and a model of knowledge production that is truly collective and empowering for lay persons and researchers alike - in other words, transdisciplinarity (Bernstein, 2015).

The term “transdisciplinarity” was first used, almost offhandedly, by Piaget in 1970 (Bernstein, 2015). Piaget (1972) points us towards a system, or more accurately, a melded view of knowledge in which there is not only reciprocal relationships among disciplines, but the boundaries of the disciplines are deeply permeable, with one discipline flowing into another (Piaget, 1972). At around the same time Jantsch (1972), Mahan (1970), Kockelmans (1979) and others discussed transdisciplinarity. As the conversation

Preface

around transdisciplinarity continued, two schools of thought emerged, spawned largely by the writings of Gehlert (2013) and Gibbons, Limoges, Nowotny, Schwartzman, Scott, and Trow (1994; Bernstein, 2015). Gehlert (2013) school of thought was about transdisciplinarity from an ethical and philosophical viewpoint. In contrast, Gibbons et al. (1994) place emphasis on real solutions for “real world” problems (Bernstein, 2015).

Though transdisciplinarity as a concept had been around for some time, strong interest in transdisciplinarity really emerged around two decades later, in the 1990’s. Interestingly, this is about the same time at which the digital revolution and the disruption it brought began in earnest. In the emerging digital globalized world with its rising complexity, the luxury of transdisciplinarity starts to be seen as necessity. Nowadays, as Bernstein (2015) notes, “Transdisciplinarity ... is characterized by its focus on “wicked problems” that need creative solutions, its reliance on stakeholder involvement, and engaged, socially responsible science. In simultaneously studying multiple levels of, and angles on, reality, transdisciplinary work provides an intriguing potential to invigorate scholarly and scientific inquiry both in and outside the academy” (Bernstein, 2015, p. 1). Transdisciplinarity is much more than simply working together with others from different disciplines, it is much more than the sharing of minds. Rather embracing transdisciplinarity is about challenging our acceptance of disciplines as units of organization for knowledge in theory, research and practice (Bernstein, 2015) – it is about a “new way of thinking and engaging in inquiry” (Muntuori, 2008, p. ix).

The discourses of transcendence, and problem solving, are aligned with transdisciplinarity (Klein, 2004). A third discourse, transgression also permeates transdisciplinarity. Positioned within the discourse of transgression, and emerging at a time when human rights accountability was a dominant social theme, transdisciplinarity is seen to yield ‘socially robust knowledge’ (Klein, 2004). From the perspective of disciplines, the dominant forms of knowledge establish ways of knowing (genres, protocols, canons etc.) that “marginalize” other ways of knowing. Transdisciplinarity combats marginalization and is conducive to more equitable knowledge production (Fam, Palmer, & Riedy, 2016).

Freed from the constraints of adhering to the norms of any particular discipline, transdisciplinarity produces knowledge by drawing on many sources of knowledge and parts of society – a heterogeneous instead of a homogenous approach (Montuori, 2011). Within transdisciplinarity, the disciplinary boundaries become unimportant and largely dissolve, as do the boundaries between the academic/expert and the layperson (Nowotny, Scott, & Gibbons, 2001). Knowledge construction from the frame of transdisciplinarity is less about who is the expert and the ‘rules’ of the discipline and more about the problem to be solved, who is involved and the context within which it is embedded. Transdisciplinarity provides fertile ground for participatory approaches wherein all voices [are] heard (Fischer, 2011); participants are equally valued and empowered to participate actively in problem solving and research is more likely to be socially relevant (Binder, 2014).

In its ideal, transdisciplinarity facilitates open systems of knowledge production, paving the way for richer ecologies of creative thought (Fischer, 2011). Creative thought is of course pivotal to the solving of highly complex problems. Creativity and innovation, along with participatory methodologies are what is required to tackle the truly difficult and highly complex problems such as climate change and sustainability. To illustrate, it is apparent in literature that sustainability and transdisciplinarity cohabitate the same spaces and have a close relationship.

Research for sustainable development has to be issue orientated and reflect the diversity, complexity and dynamics of the processes involved as well as their variability between specific problem situations...

knowledge of people involved and their needs and interests at stake have to be taken into account. (Haddorn, Bradley, Pohl, Rist, & Weismann, 2006, p. 119)

Highly complex problems such as sustainability necessitate building a culture of ‘democratic’ participation. This is necessary where problems may be so large that individuals or even large teams are unable to solve, or problems that are ill-defined or poorly understood requiring a pooling of minds (Fischer, 2011). Further exemplifying the application of transdisciplinarity to complex problems, are works such as that by Gehlert (2013). In discussing the health disparities (heart disease, diabetes, cancer and HIV) experienced by the “most vulnerable residents” of United States, Gehlert (2013) positions transdisciplinarity as not only a realistic aim for inquiry but also a “necessary one” (p. 1). Gehlert (2013) points out that thus far the United States Government has failed to address the disparities, mostly not through lack of effort but through inadequate approach to inquiry. Gehlert (2013) states:

Executing successful disparities research depends on the ability to visualize the multiple influences on health and health disparities and understand the complex ways in which they interact with one another to produce worse outcomes for some groups than others. This can be done neither by a single investigator nor by a single discipline. (p. 2)

Gehlert (2013) argues that the impediment to progress is the lack of transdisciplinary research and goes on to articulate some of the issues and approaches, which foster the required approach. Like Gehlert, others hold the view that through a culture of participation, transdisciplinarity “democratizes design and innovation, shifting power toward users” to develop real-time, socially relevant systems of use (Fischer, 2011, p. 44).

For the time being transdisciplinarity is, as Piaget (1972, as cited in Klein, 2004, p. 1) observed, is “still a dream”. If transdisciplinarity’s potential is to be truly realized (and not remain rhetoric), then new methods, practices and paradigms are required. Transdisciplinarity, for all its potential advantages, is problematic. It requires not merely a shift towards more collaborative methods, but rather a transformation of thought and practice. It is literally a ‘new way of thinking’ which must be achieved. The way researchers have proceeded in the past may no longer be the best way or yield the greatest benefit. A major challenge is therefore to achieve a transformation of practices and methods. There is a need for new theoretical, conceptual and practice orientated approaches (Blassnigg & Punt, 2013). Transdisciplinarity requires evolution of thought and a great deal of reflection on the methods, processes and approaches of transdisciplinarity. There is a need for “methodological frameworks to forge innovative approaches to research collaboration that is inquiry-driven and seeks to identify new topics and concerns” (Blassnigg & Punt, 2013, p. 3). From this perspective, transdisciplinarity is something more than a problem driven approach for unifying disparate disciplines of knowledge. The inquiry itself drives methods and tools and precipitates previously unidentified areas of concerns (Blassnigg & Punt, 2013).

Transdisciplinarity is therefore not only a way by which to address complex or ill-defined problems, but also a way of identifying new problems that in the past have not been recognized or that are being newly generated by the evolving system (Blassnigg & Punt, 2013). The obvious challenge of transdisciplinarity is moving beyond established institutional frameworks. Rather than being merely established repositories of knowledge, universities must reformulate themselves as enablers of participatory approaches.

Transdisciplinarity challenges the established structure of knowledge and to some extent shakes the very foundations of university bureaucracy. Despite the generally positive support for transdisciplinar-

ity, it is mostly relegated to the domain of rhetoric. To illustrate, consider that while transdisciplinary reviewers of grant and other funding applications value approaches. The assessment of grant applications still relies heavily on the word of ‘experts’ (Blassnigg & Punt, 2013). Consider also that promotion and career tracks are based largely on performance standards as dictated by professional organizations. The processes remain rooted in the marginalization of knowledge outside the academy. From the pragmatic perspective, the challenge is devising tools and methods, which will enable the synthesis of knowledge in the manner of transdisciplinarity. A move towards ‘pragmatic transdisciplinarity’ is seen in literature and is reflective of the need to establish more strongly a practical dimension.

At the practical individual level, engaging in transdisciplinarity requires teams to negotiate shared conceptual frameworks and ways of knowing (Gehlert, 2013). Hence one of the challenges faced by individuals engaging in transdisciplinarity is establishing communication and trust. Working beyond disciplines, team members must establish a shared lexicon (Gehlert, 2013). Functioning within a transdisciplinarity setting may not come naturally but rather requires training and education alongside institutional support (Gehlert, 2013). Gehlert (2013) articulates a need for transdisciplinarity in higher education: “The transdisciplinary approach will be an indispensable complement to the disciplinary approach” (p. 17). Bringing Transdisciplinarity into education is an important step in building a culture of transdisciplinarity. Interestingly, transdisciplinarity in the manner presented by Gehlert (2013) is more complementary rather than contradictory to the traditional disciplinary view. The argument for imbuing education with transdisciplinarity is pointed:

All the various tensions—economic, cultural, spiritual—are inevitably perpetuated and deepened by a system of education founded on the values of another century, and by a rapidly accelerating imbalance between contemporary social structures and the changes which are currently taking place in the contemporary world. More or less embryonic wars between economies, cultures, and civilizations never stop leading, here and there, to actual wars. In fact, our entire individual and social life is structured by education. Education is at the center of our becoming. The future is shaped by the education which is delivered in the present, here and now. (Gehlert, 2013, p. 20)

Gehlert’s (2013) perspective puts a slightly different lens on transdisciplinarity and the institutional challenge of its adoption. Transdisciplinarity is not a discipline in itself and researchers working in the transdisciplinary space are not “transdisciplinary experts” says Gehlert (2013, p. 25), so there is no necessity to create new departments and or new chairs. It is better to promote a ‘spirit of transdisciplinarity’ through workshops and communities of practice where the transdisciplinary attitude can be nurtured and infused throughout the institution so that a tolerance, or even appreciation, of transdisciplinarity can evolve.

For anyone considering moving outside of the disciplinary boundaries they are likely to be confronted with institutional, individual, epistemological, or methodological challenges (Darbellay, 2015). Though often promoted, transdisciplinarity is not always recognized as a “form of research in its own right” (Darbellay, 2015, p. 163). As Foucault (1971, as cited in Darbellay, 2015) states a discipline is “defined by groups of objects, methods, their corpus of propositions considered to be true, the interplay of rules and definitions, of techniques and tools” (p. 32). With this conceptualization of a discipline, the discipline provides structure and rigor, and controls the research process. For some, moving beyond the boundaries of the discipline is contradictory to the established view of scientific research and is even suggestive of sacrificing the rigor and needed structure of research thereby challenging legitimacy. As Darbellay (2015) astutely observes academics working on or outside the boundaries of disciplines are taking a risk. They have the profile of a ‘transdisciplinary hacker...who would like to change academe

from within without causing its collapse” (p. 172). These ‘transdisciplinary hackers’ should be supported (Darbellay, 2015). Their willingness to take the risk of venturing into largely uncharted ‘waters’ to help investigate the potential of transdisciplinarity needs to be valued.

Thus far we have highlighted the facets of transdisciplinarity as complex, disruptive, transformative, unifying, challenging, legitimizing and empowering. Racialized, gendered and classed, the need to promote a more just society is a pressing but also a very complex issue. This is just one ‘wicked’ problem facing humanity in which transdisciplinarity seems an appropriate approach to inquiry. Engaged in searching for ways to solve complex problems and situations, practitioners and researchers rely on a base of the scientific method popularized by John Dewey (1916), and on the three kinds of knowledge (instrumental, practical and emancipatory) advanced by Jurgen Habermas (1971). Anchored on these existing methods, researchers and practitioners commonly need to forge bridges across multiple disciplines in order to solve complex problems and situations. ‘Transdisciplinary theory’, the idea of working across disciplines is not new. Our profession has always advocated multidisciplinary and rhetorically interdisciplinary approaches as ways to solve problems that occur from generation to generation. However, the profile of transdisciplinary theory is now raised to new heights. Knowledge creation is identified as being of the utmost importance to a surviving and thriving human society in the 21st century and beyond (the new edition of Bloom’s 1956 as cited in Krathwohl, 2002) taxonomy identifies knowledge creation at the highest level), and we are turning to the epistemology of transdisciplinarity in order to generate the needed knowledge to solve complex problems and move towards a more positive, socially robust future for all.

The traditional methods of viewing the world through the scientific method or instrumental knowledge do not adequately serve the needs of theory, research and practice within an increasingly complex world. Through transdisciplinary theory, research and practice, academics focus on a new form of learning and problem solving involving cooperation among different parts of society to meet the complex challenges of society. No longer can academics afford to work within the imagined boundaries of disciplines and ignore the power of mutual learning, and the insights which may arise from the interaction of knowledge of all participants. Practical knowledge or the dialogue between academia and other parts of society create new interactions and new results, offering a new vision of nature and reality. Intricate societal problems are interwoven and the future requires co-creation of knowledge in the manner of transdisciplinarity (Binder, 2014). Transdisciplinarity may be considered a Utopian idea, but it is a new way of thinking that challenges established institutional, individual and methodological norms. Transdisciplinarity is an attitude, a state of mind. Exploring, understanding and building a culture of transdisciplinarity requires ongoing discussion alongside more pragmatic exploration by ‘taking the risk’ of venturing forth.

OBJECTIVE OF THE BOOK

Handbook of Research on Transdisciplinary Knowledge Generation will feature full length articles (7,000 to 10,000 words) authored by leading experts offering an in-depth description of concepts related to transdisciplinarity in theory, research and practice in this changing society. The multiple volume book will serve as the comprehensive and best resources for teaching, learning, research and application across disciplines. Offering a diversity of thought on transdisciplinarity, the book will serve as foundations for scholars and practitioners to generate knowledge from across the disciplines. The book will be a milestone handbook of research, attracting intellectual attention from around the globe. Every researcher’s horizon will be widened by using this book as a reference source.

Preface

TARGET AUDIENCE

The book will be appropriate for university libraries, dissertation libraries and national libraries from around the globe. Individual departments and colleges may also need to catalog this book.

Victor X. Wang
Liberty University, USA

Geraldine Torrisi-Steele
Griffith University, Australia
